Dark matter

Glossary

- **Dark:** cannot see it / it does not shine
- **Matter:** do not have a better word to describe it (but gravity does affect it!)

Galaxies are missing some matter

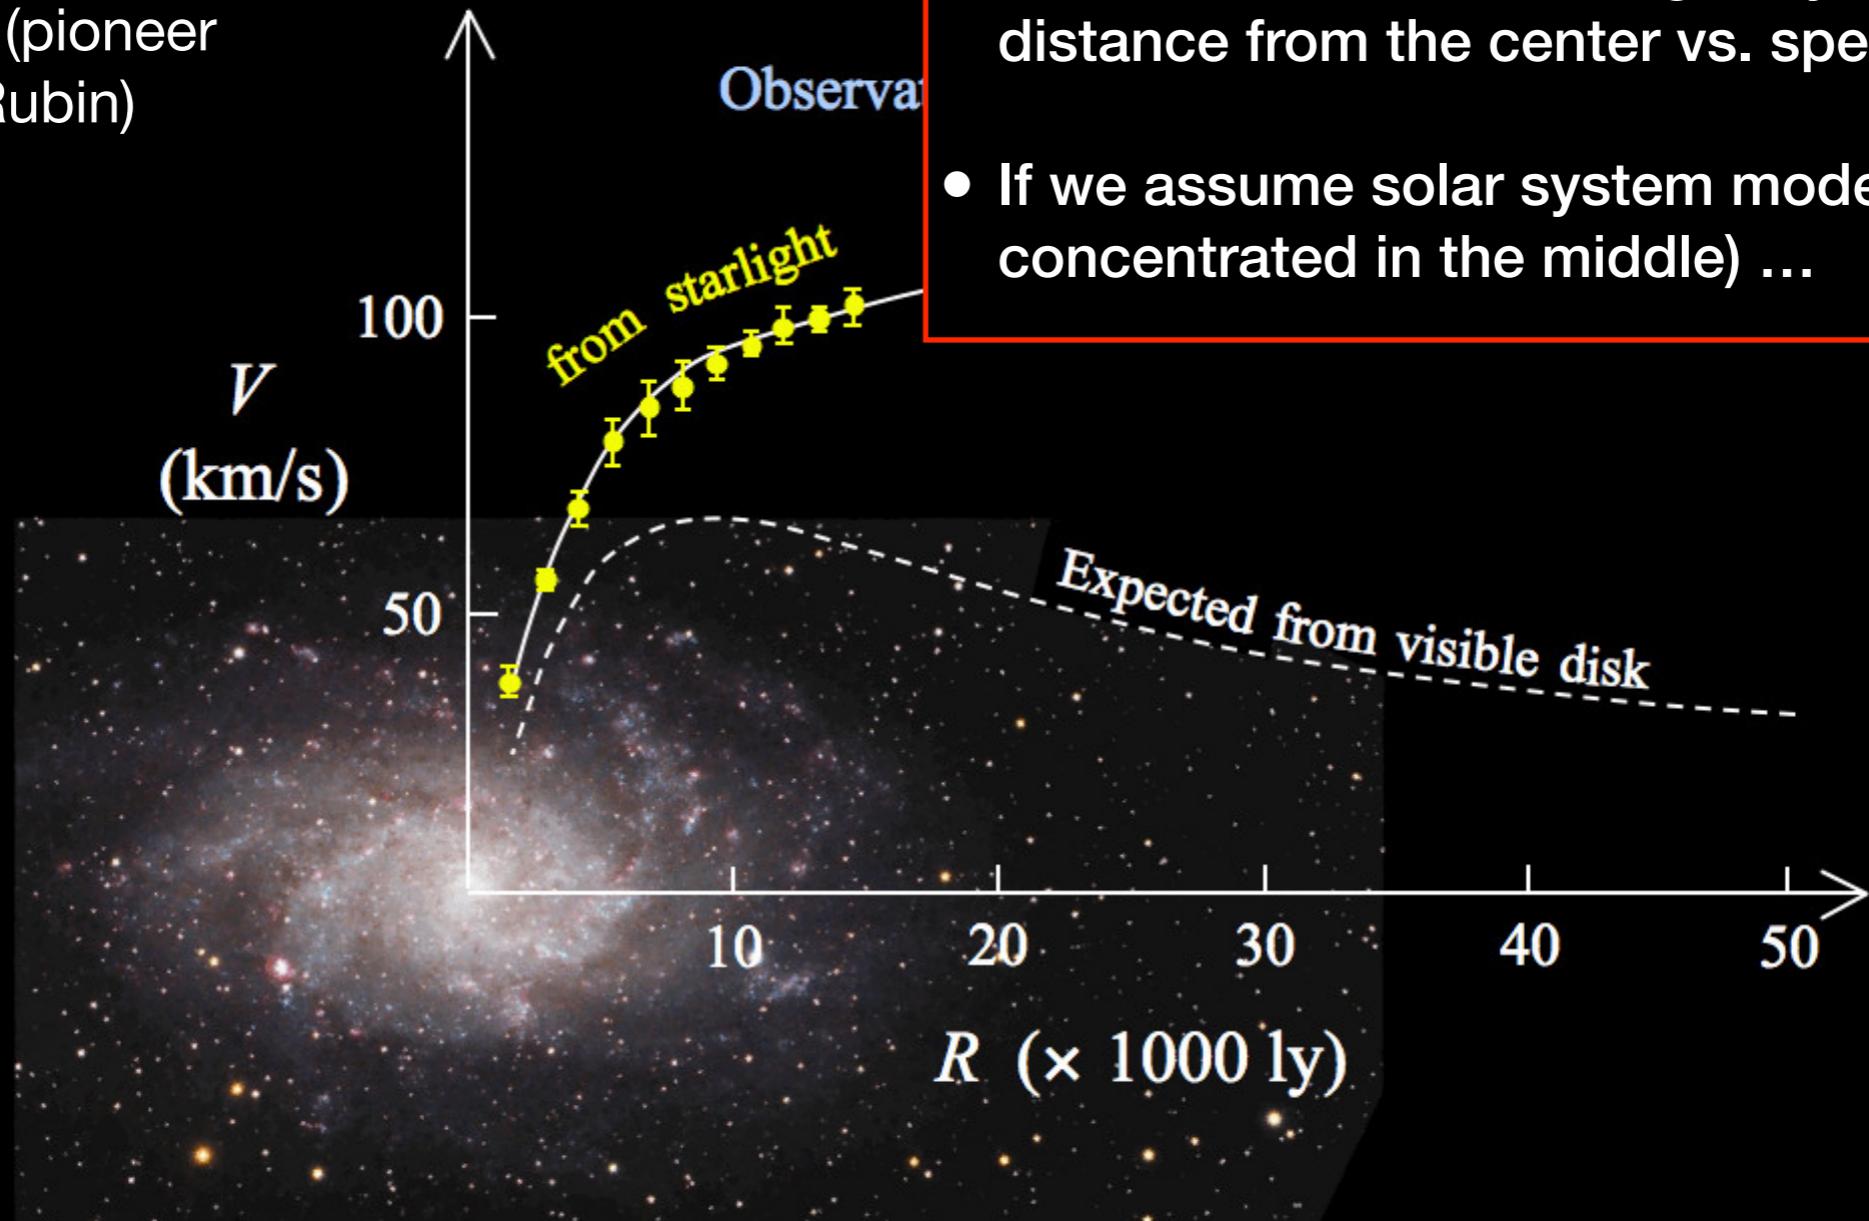

- Galaxies are the smallest cosmological scale where we can observe dm
- **Rotation curve:** mean distance from the Sun of a planet vs. average velocity
- Look at solar system where all the mass is located in the center

Galaxies are missing some matter

Spiral galaxies: more matter than meets the eye

Galaxies rotation curves measured since 1970 (pioneer was V. Rubin)

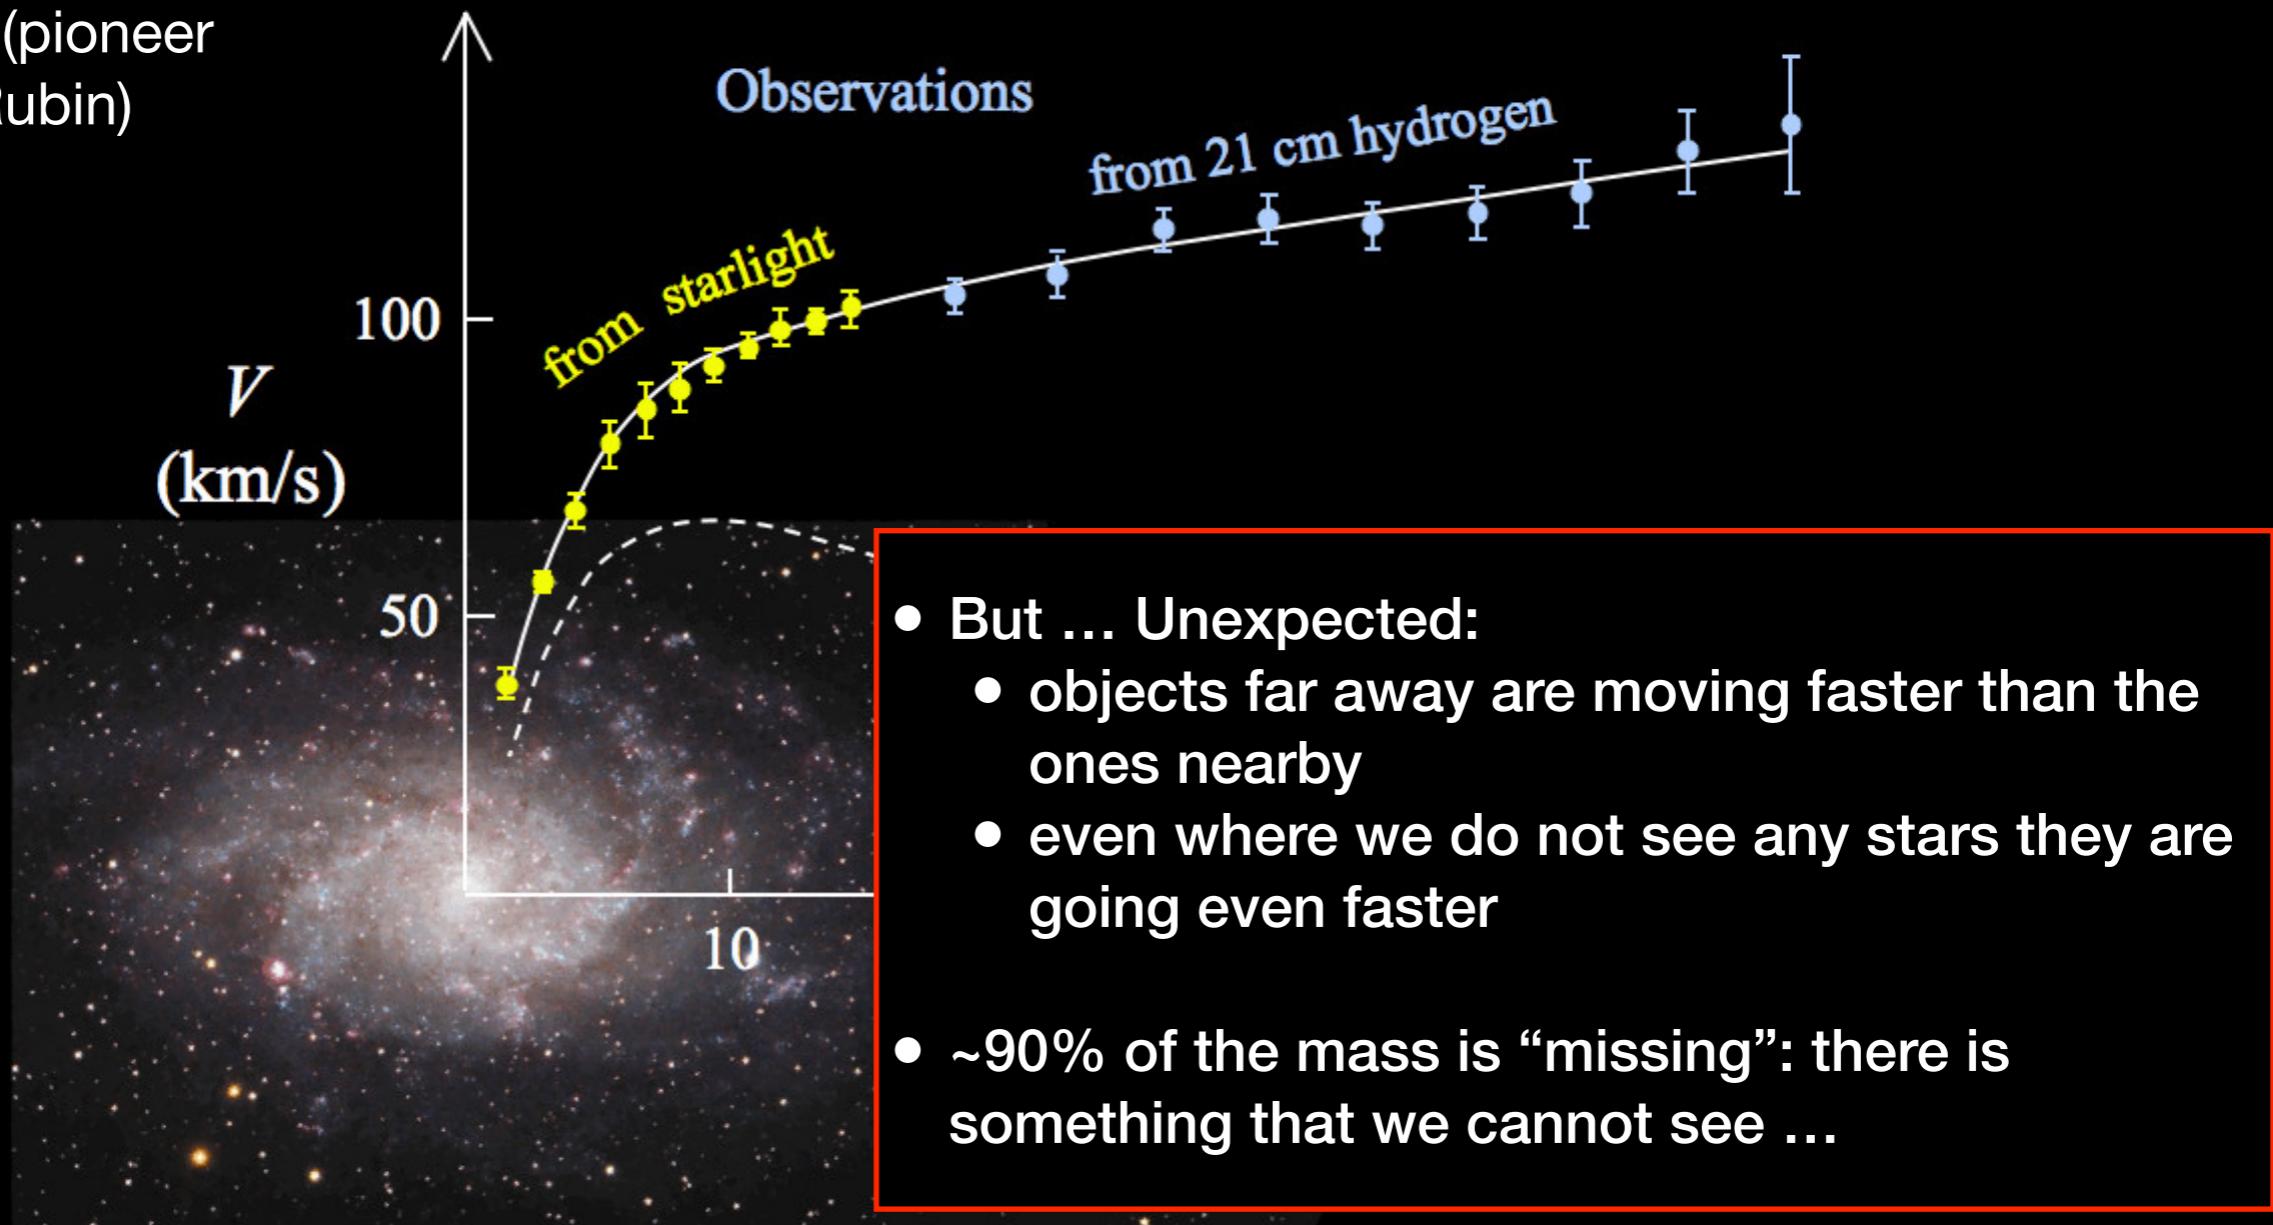

- Look at all the stars in a galaxy and measure distance from the center vs. speed
- If we assume solar system model (mass concentrated in the middle) ...

Galaxies are missing some matter

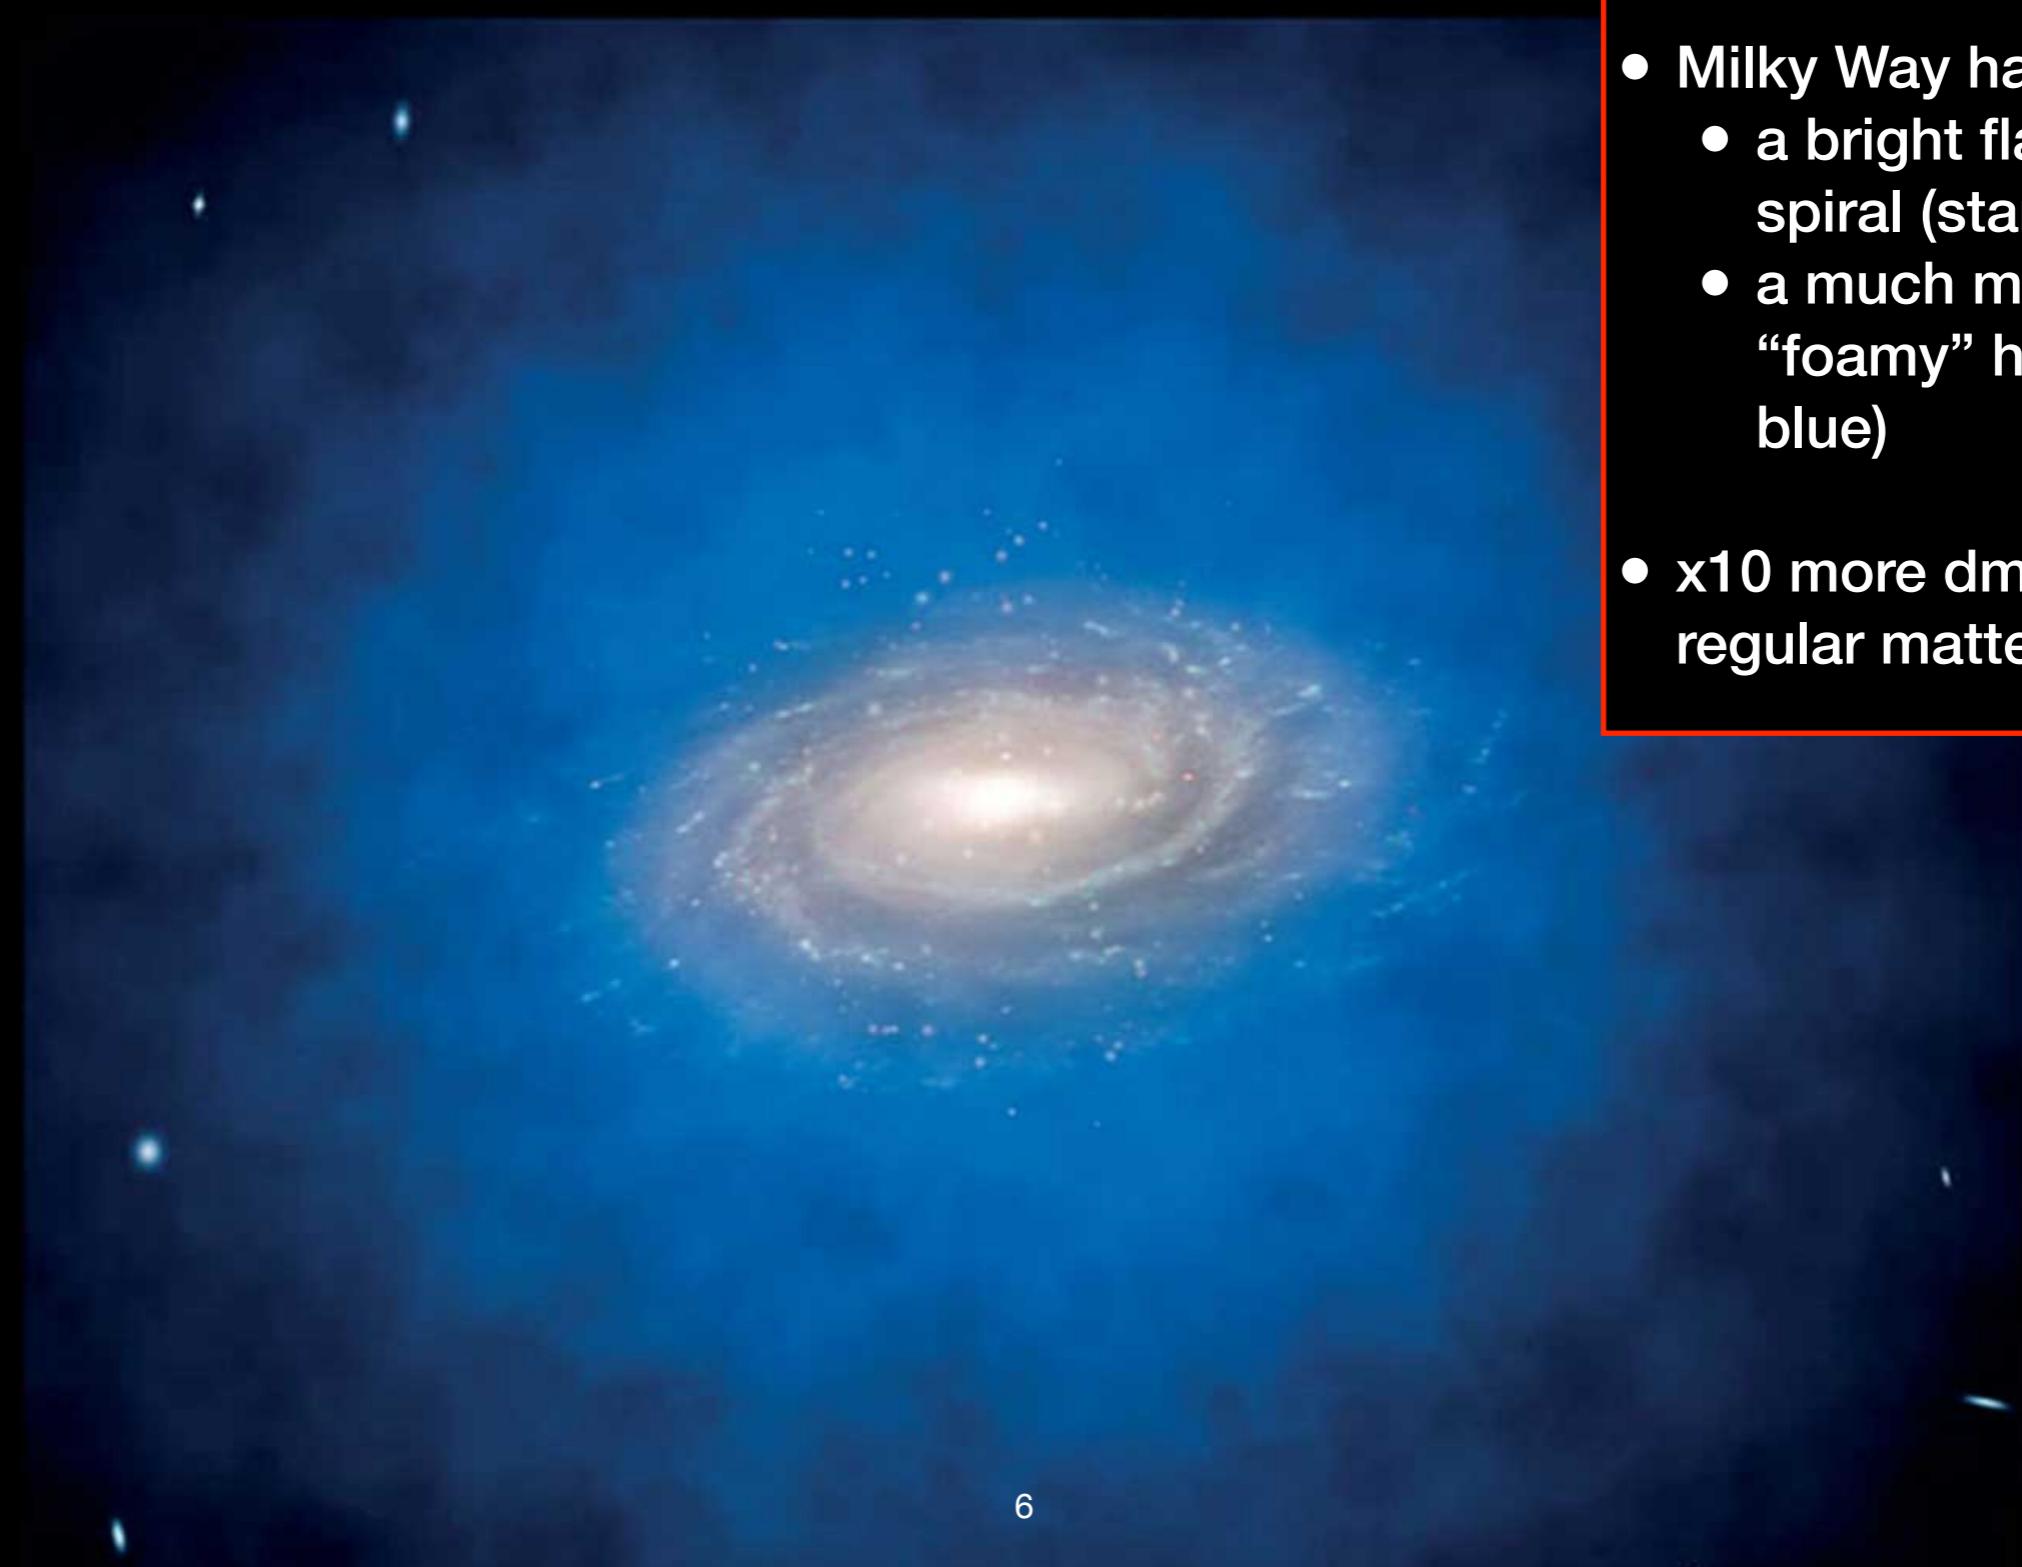

Spiral galaxies: more matter than meets the eye

Galaxies rotation
curves measured
since 1970 (pioneer
was V. Rubin)

Galaxies are missing some matter

The milky way seen with dm glasses

- Milky Way has
 - a bright flat circle/ spiral (stars)
 - a much much larger “foamy” halo (in blue)
- x10 more dm than regular matter

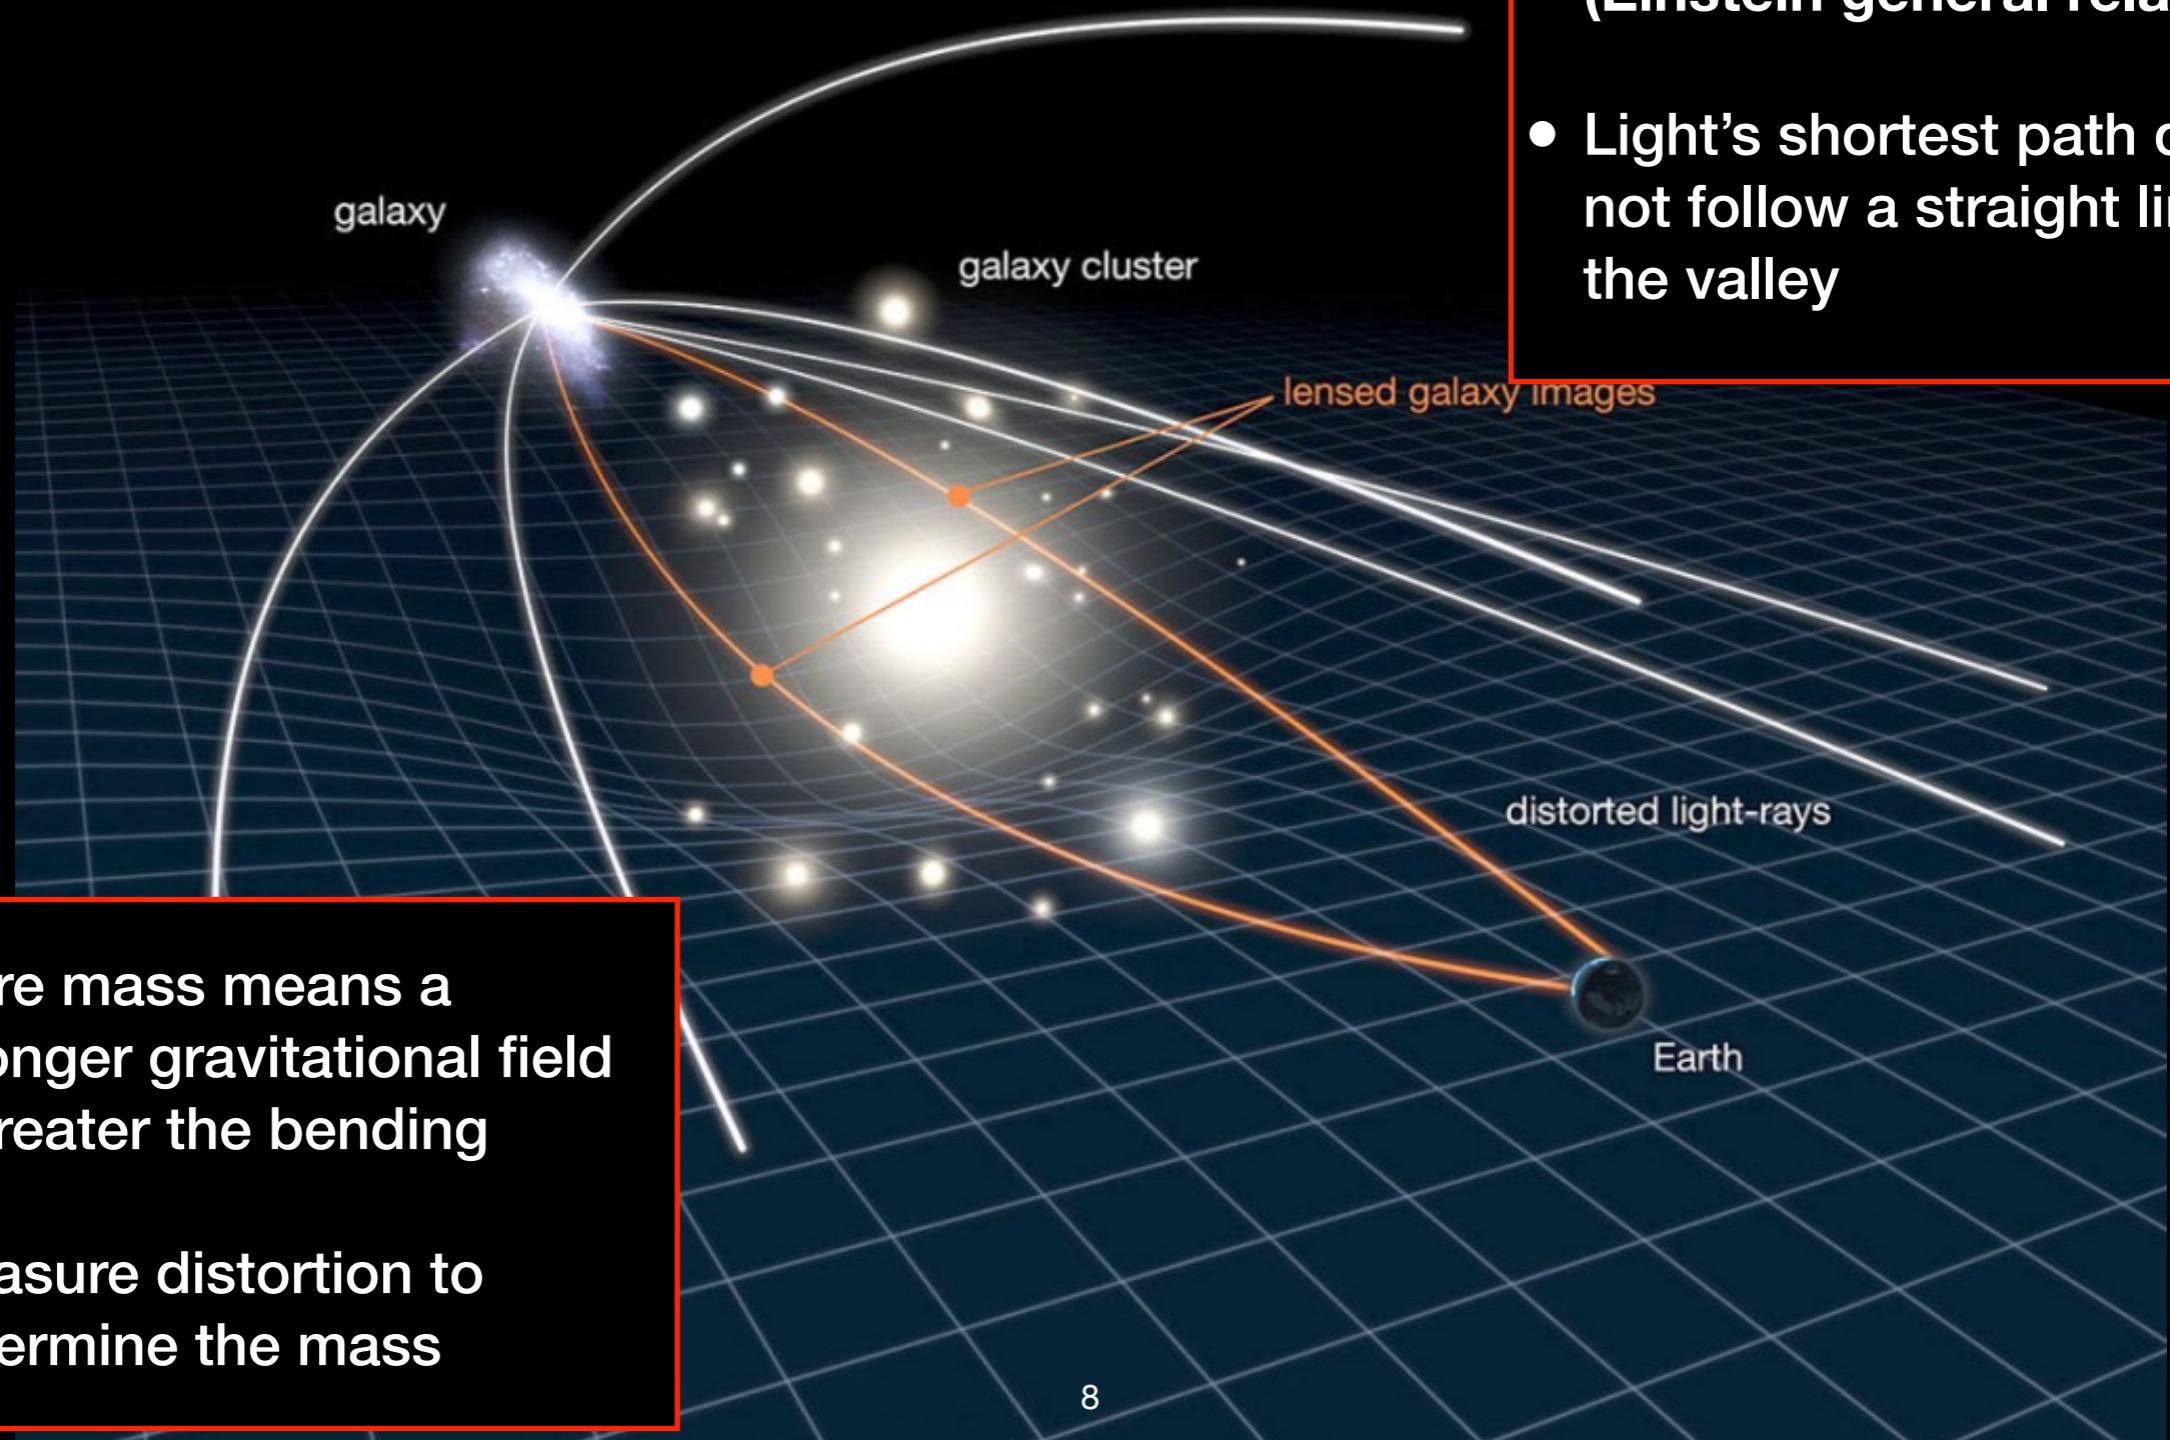

Galaxy clusters are missing some matter too

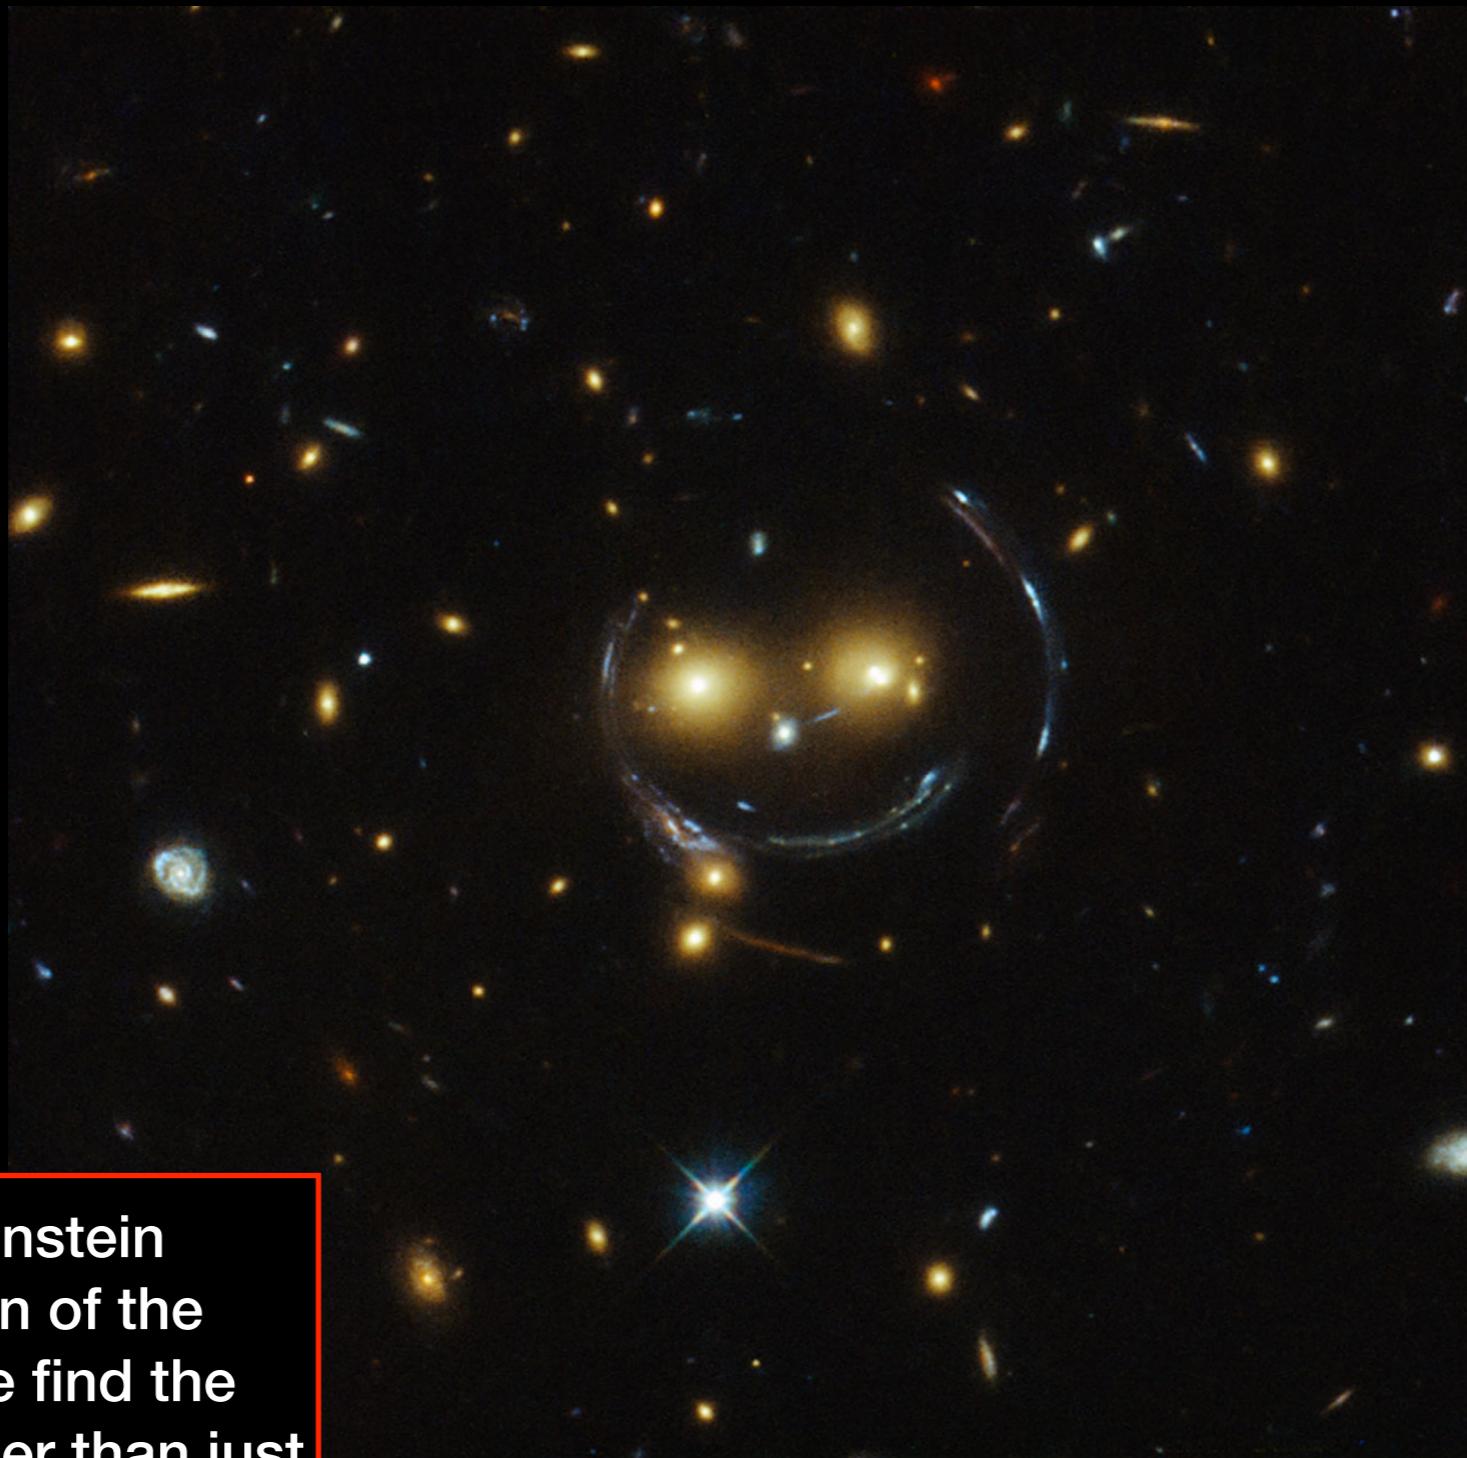

- Increasing the scale to cluster of galaxies
- A cluster contains 100 of thousands galaxies
- How do we see dm?

Galaxy clusters are missing some matter too

Gravitational lensing

Galaxy clusters are missing some matter too

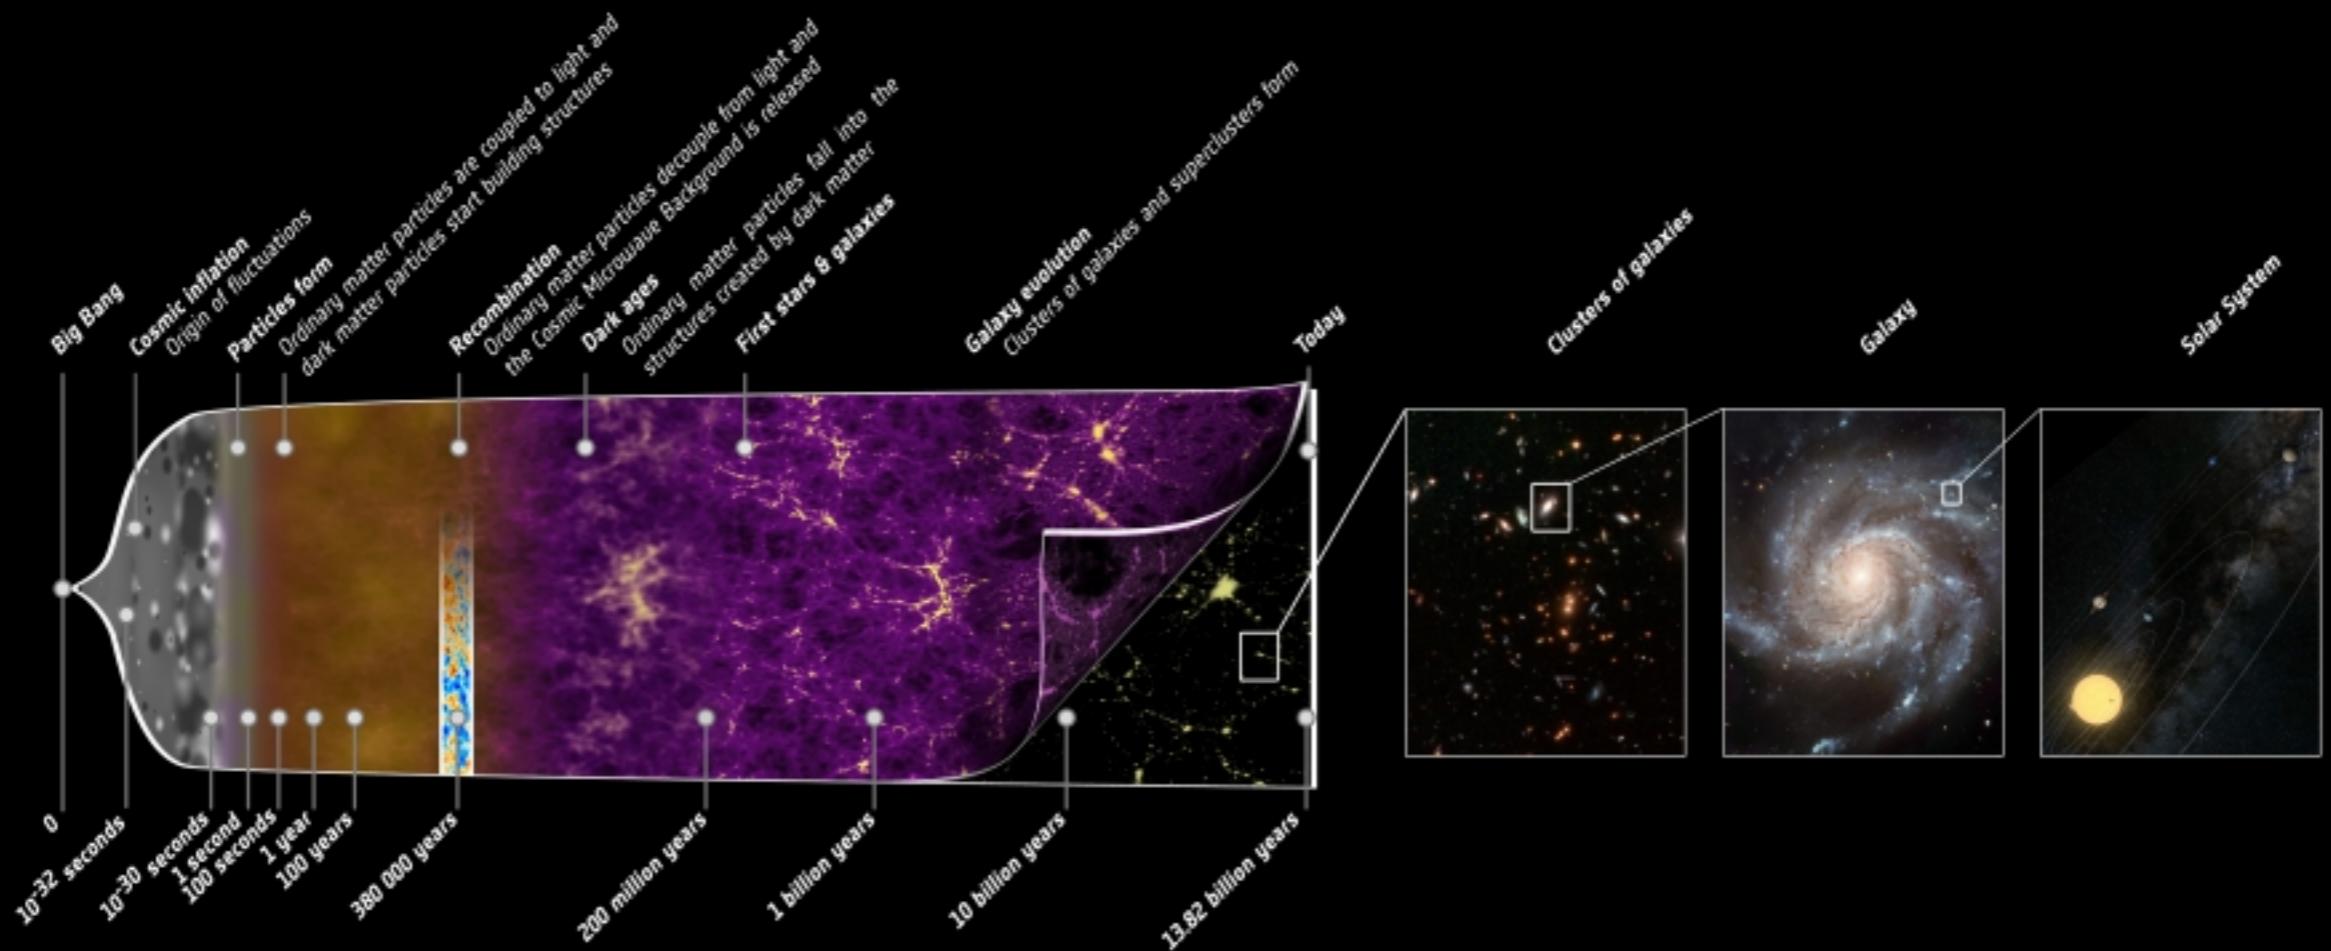

- Measuring the Einstein ring / deformation of the galaxy image, we find the mass is x10 bigger than just the stars

What about the whole Universe?

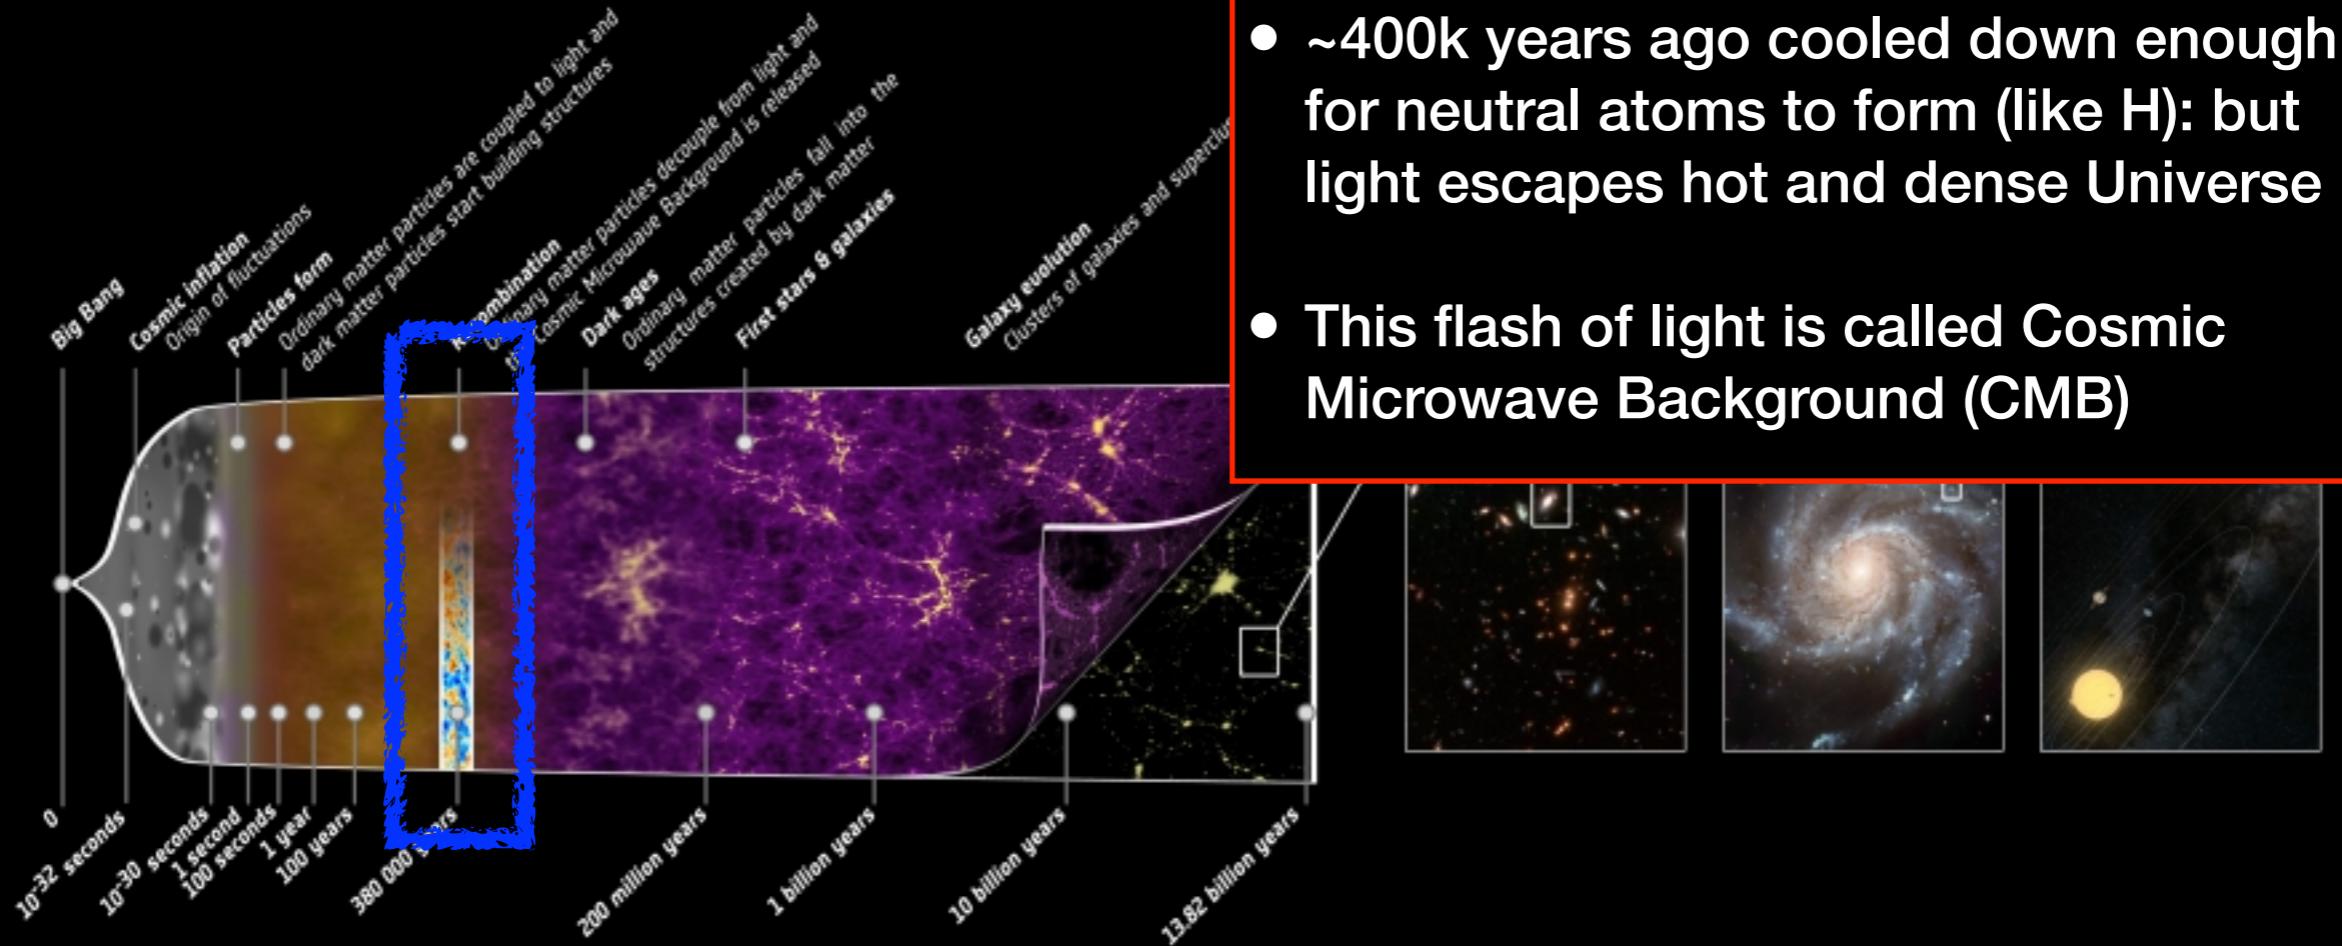

What about the whole Universe?

Brief history of the Universe

What about the whole Universe?

Brief history of the Universe

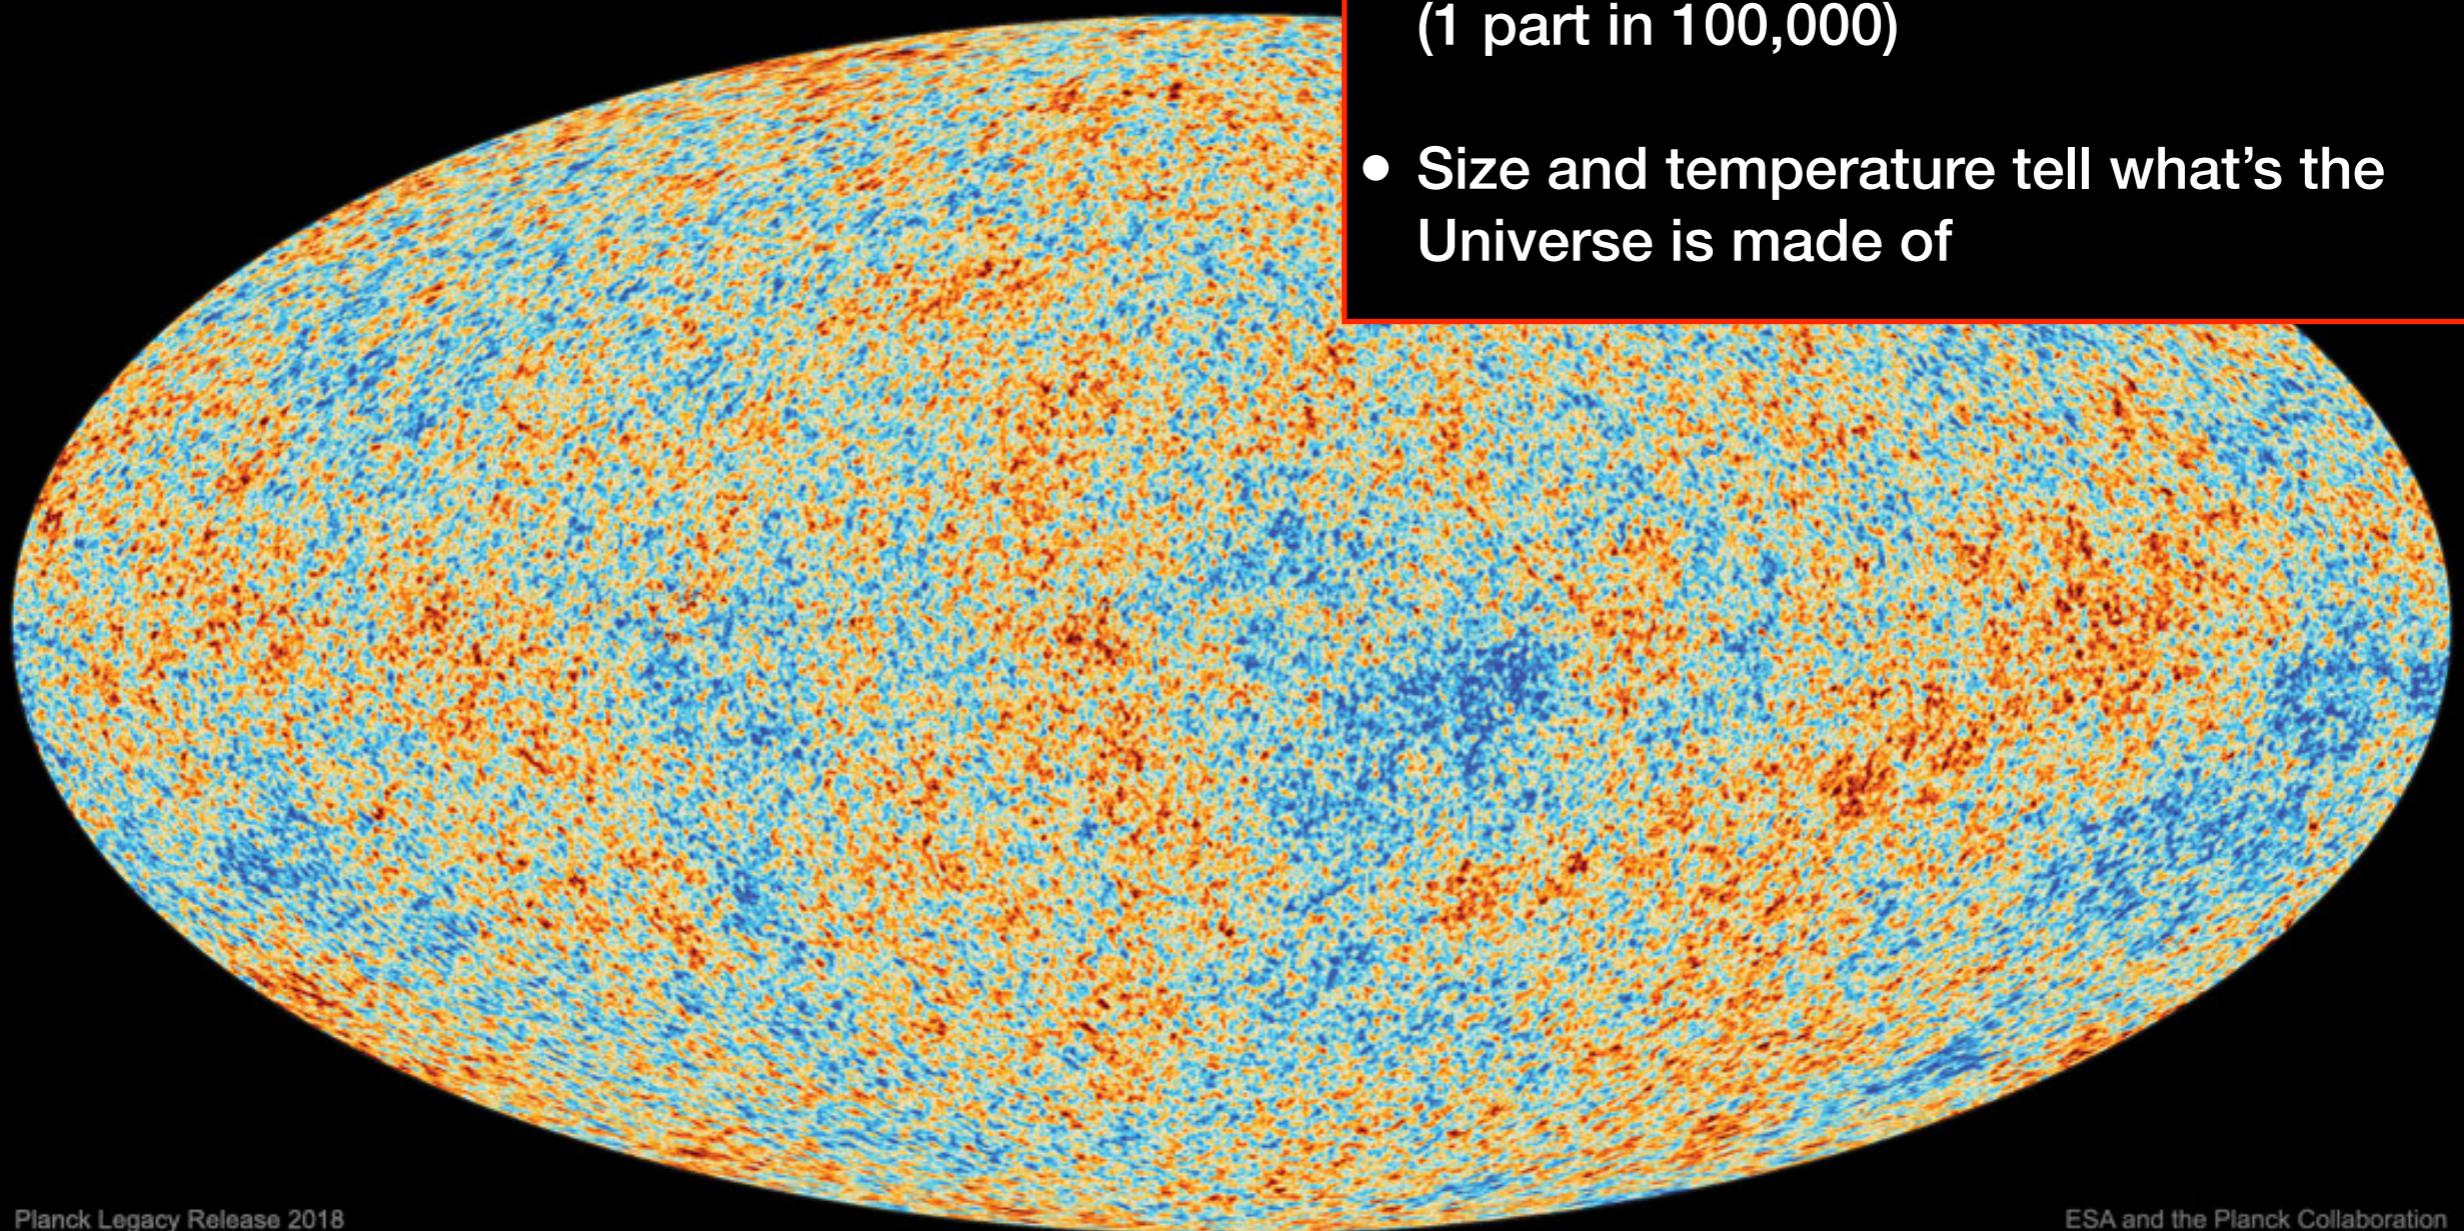

- During the Big Bang, Universe expanded faster than the speed of light and then started to cool down

- ~400k years ago cooled down enough for neutral atoms to form (like H): but light escapes hot and dense Universe
- This flash of light is called Cosmic Microwave Background (CMB)

What about the whole Universe?

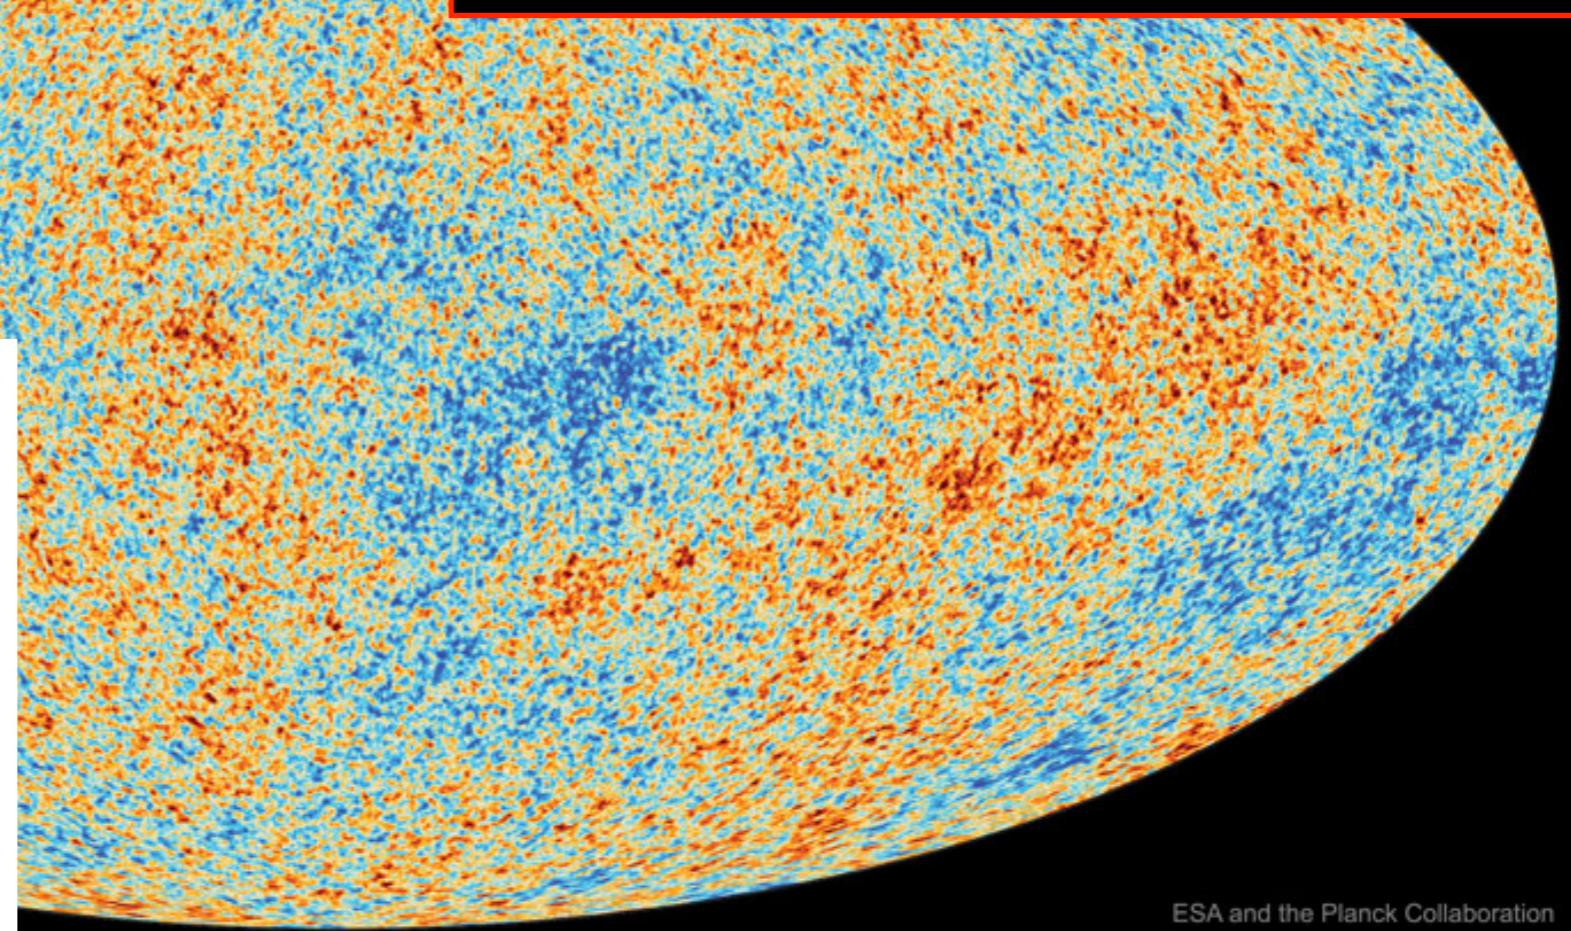

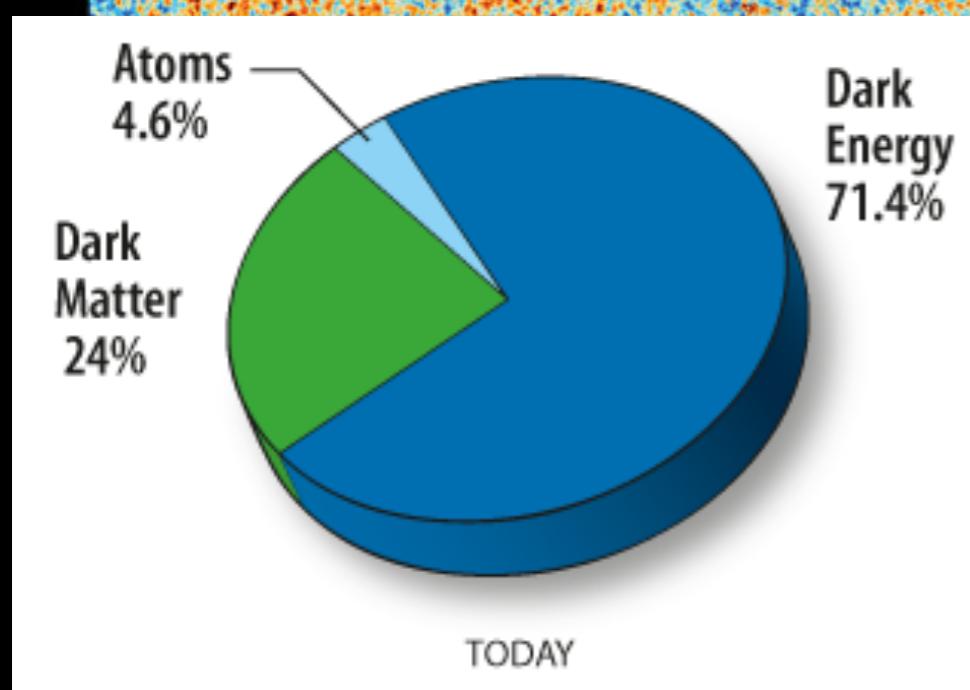

Brief history of the Universe

What about the whole Universe?

Brief history of the Universe

- Regions slightly colder or slight warmer (1 part in 100,000)
- Size and temperature tell what's the Universe is made of

ESA and the Planck Collaboration

What is dark matter?

Let's start from what it is NOT

Standard model of particle

Quarks	2.4 MeV/c ² $\frac{2}{3}$ $\frac{1}{2}$ u up	1.27 GeV/c ² $\frac{2}{3}$ $\frac{1}{2}$ c charm	171.2 GeV/c ² $\frac{2}{3}$ $\frac{1}{2}$ t top	0 0 1 γ photon	? GeV/c ² 0 0 H Higgs boson

- Gravitationally interactive
- Not short lived
- Not light mass/hot
- Do not emit/absorb light (dark)
- It must be a **NEW PARTICLE**, maybe a WIMP (Weakly Interacting Massive Particle)

Recap: so what do we know about dm?

- There's lot of dm (x10 more than regular matter)
- It formed during the Big Bang: a lot of energy created a lot of particles
- If we rewind the Universe's story, dm was interacting with ordinary matter ($dm \leftrightarrow$ regular matter)
 - Any chance dm could interact again with regular matter?
Maybe

Three ways to look for dm

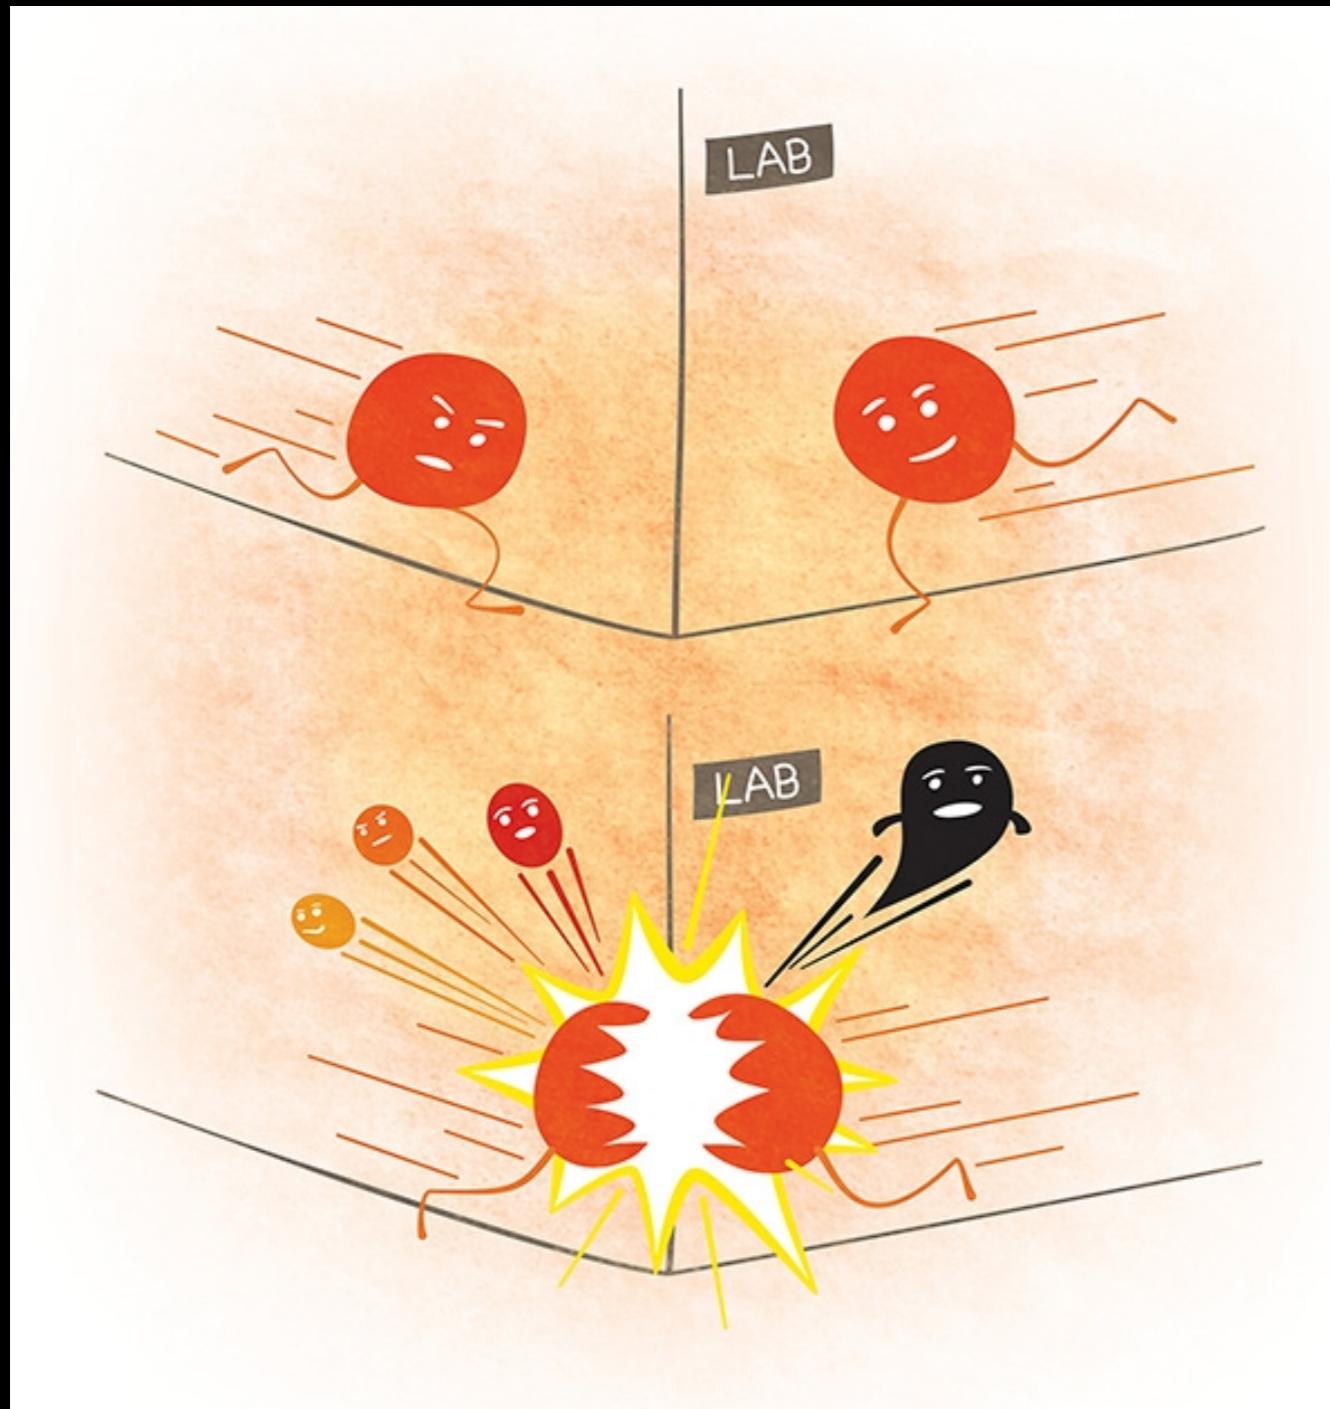

3. Going bump
underground

1. Encounters in the
lab

2. Tracking knockouts
in the space

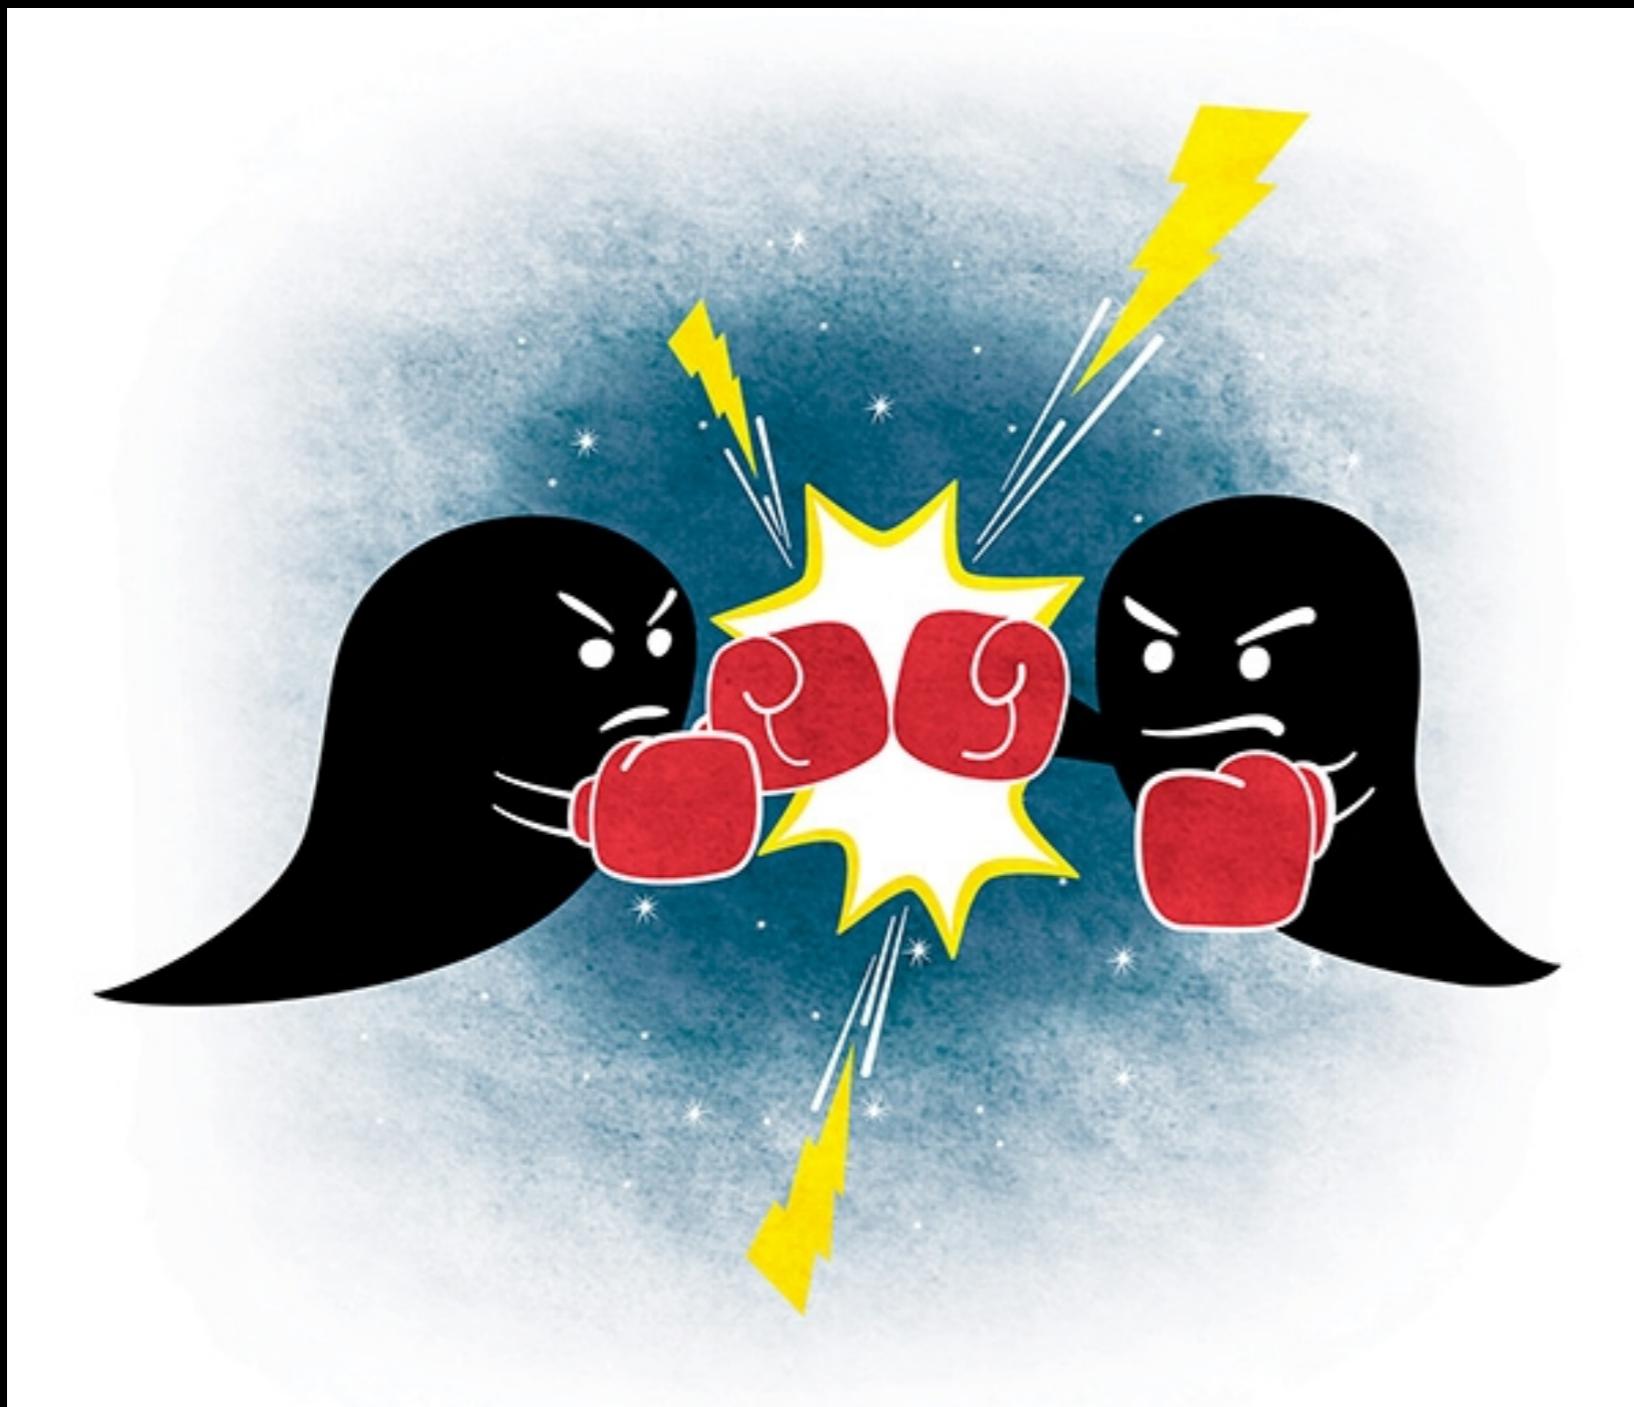

Encounters in the lab

Particle accelerators

- Particle accelerator (like at CERN) can produce dm by smashing ordinary matter (like protons)
- How to see dm?
- As unbalanced energy in the collision

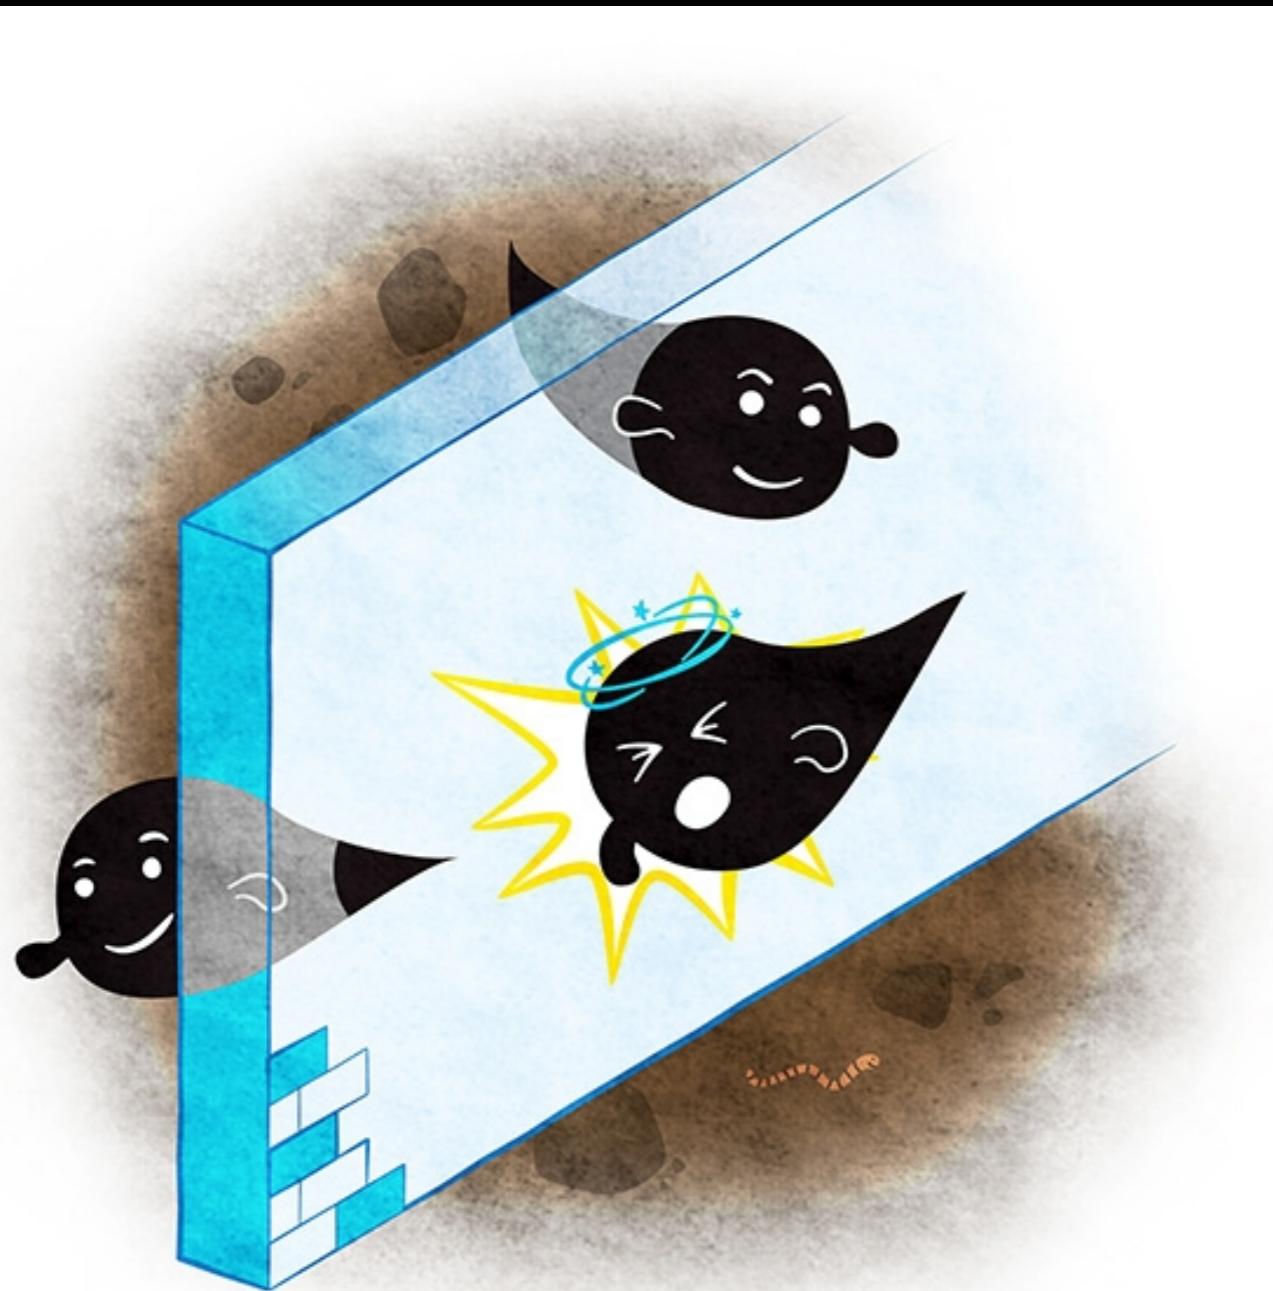

Tracking knockouts in the space Satellite

- Use Universe as particle accelerator, and look for the remains of dm collision
- Two dm particles annihilate in gamma rays
- How to see dm?
 - Look for excess

Going bump underground

Underground lab

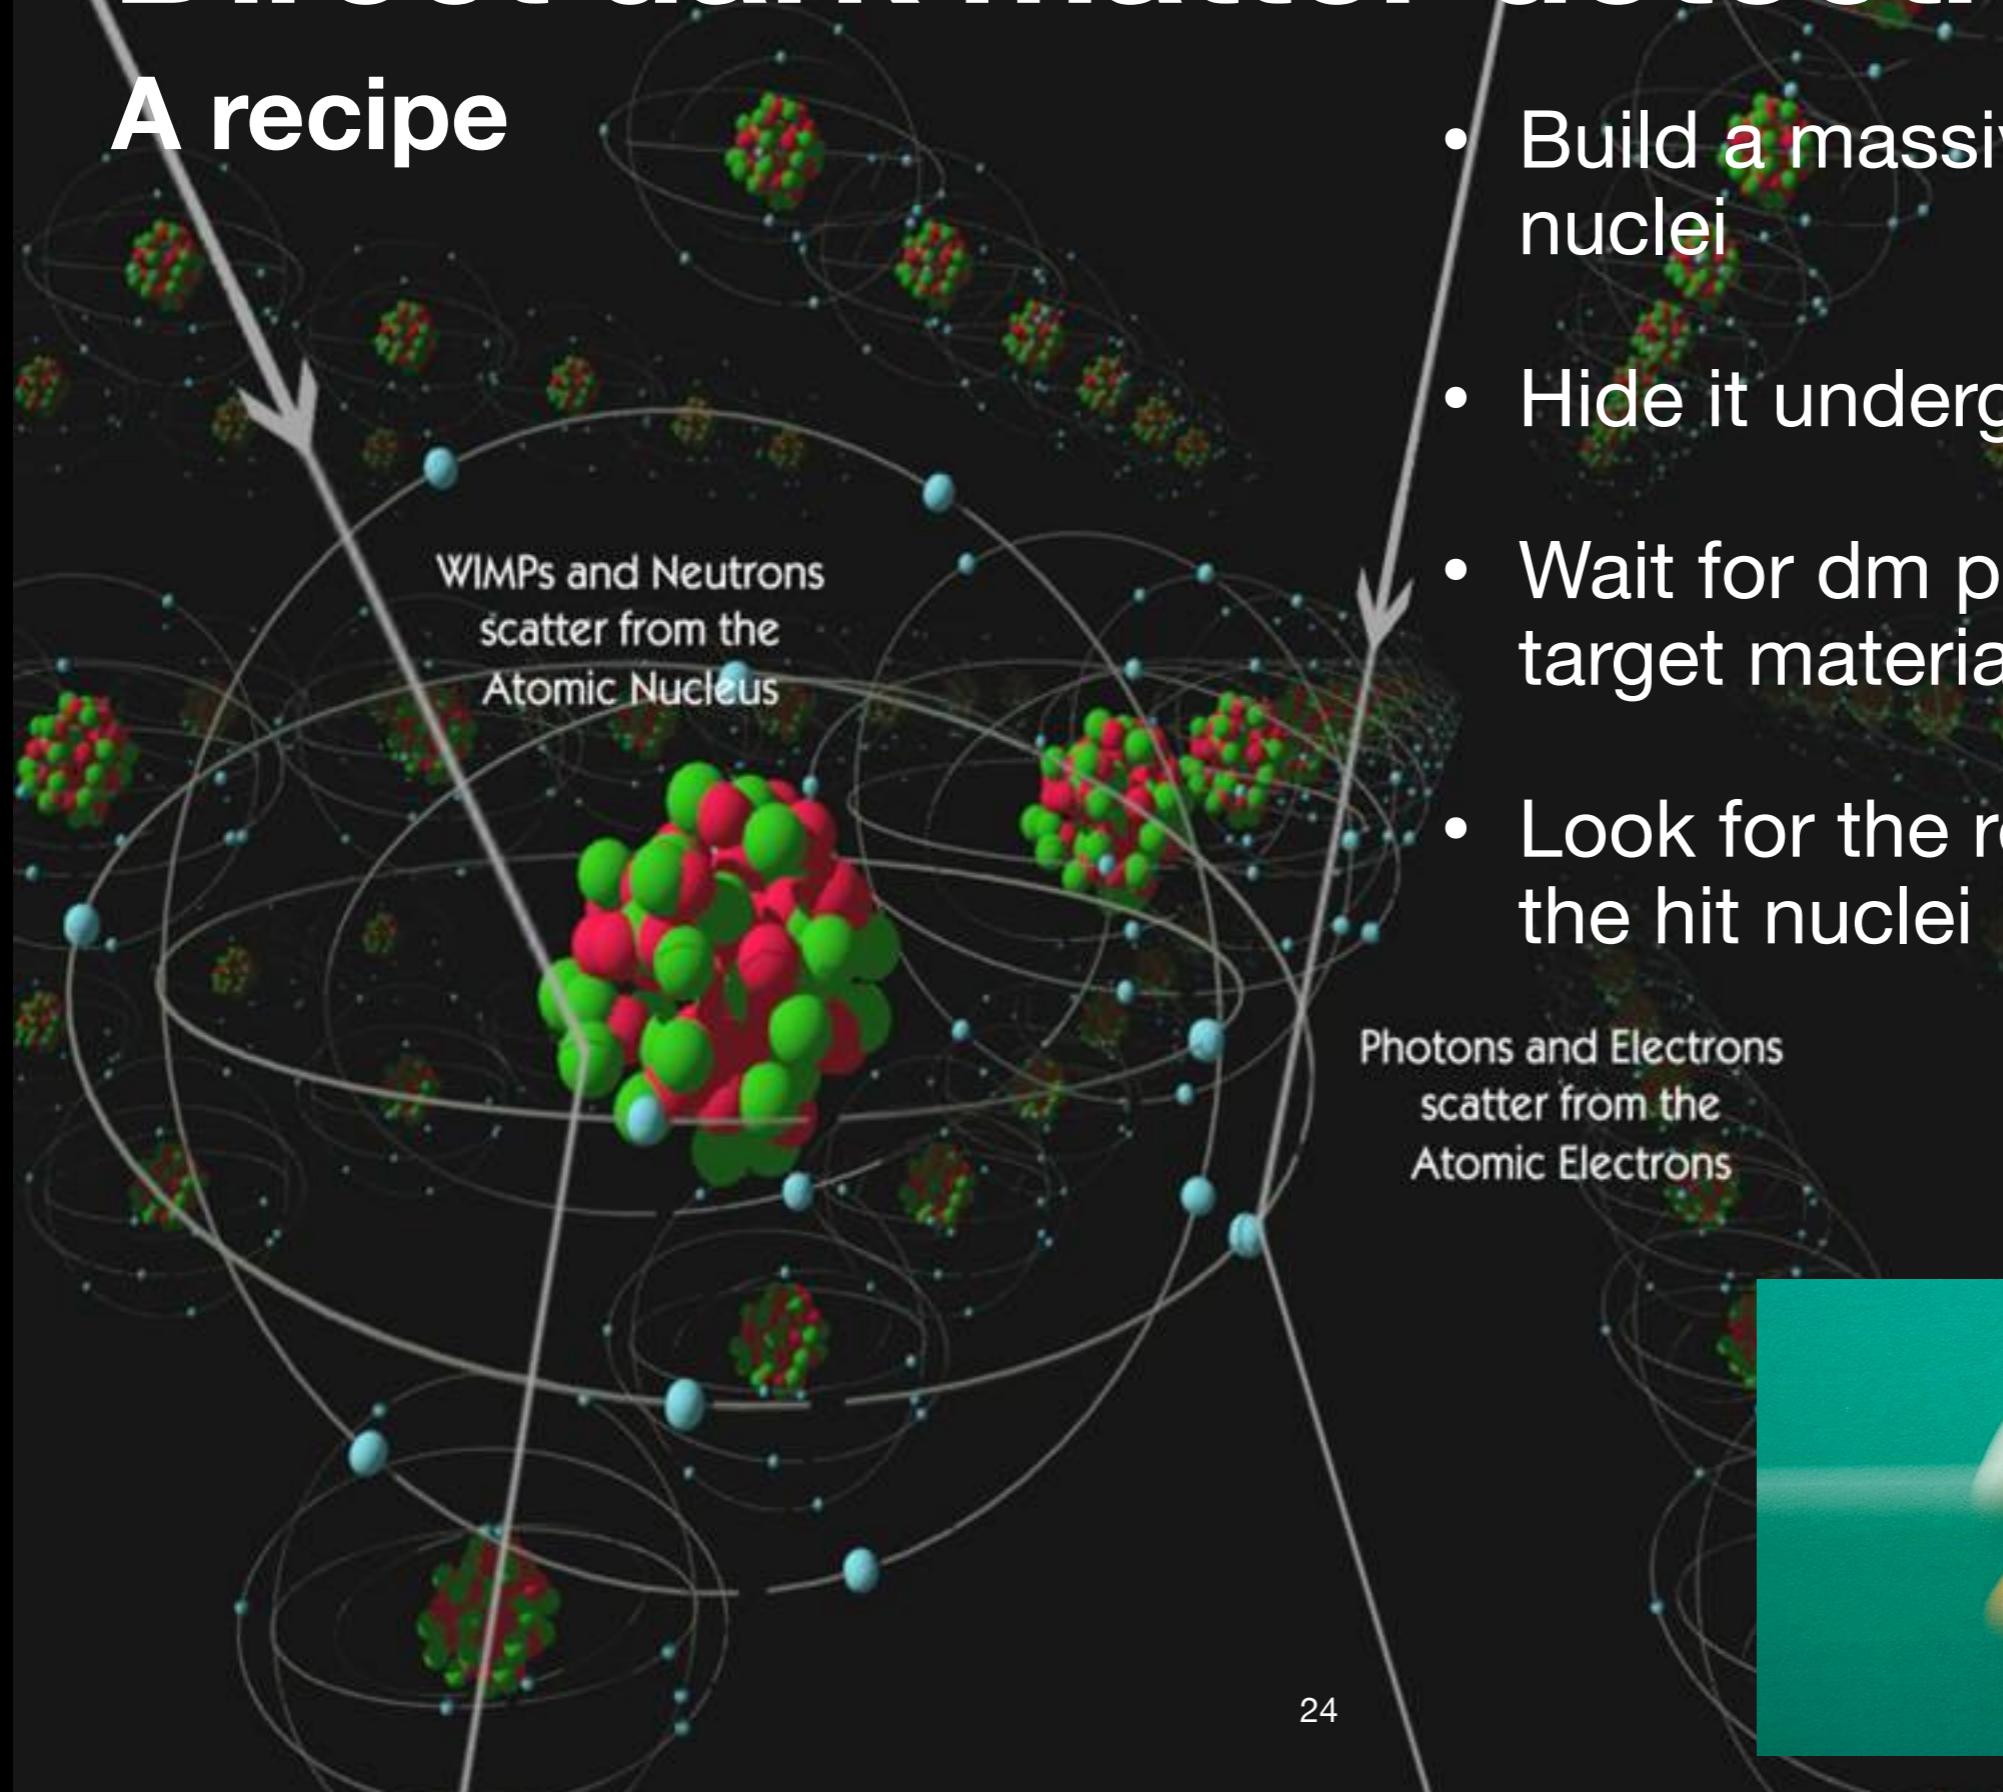

- Dm could bump into ordinary matter in lab
- Very unlike event: need to suppress any unrelated signal which can mask/mimic
- Need extremely sensitive detector located underground
- Earth's surface can be a filter to suppress all unwanted signals

Direct dark matter detection

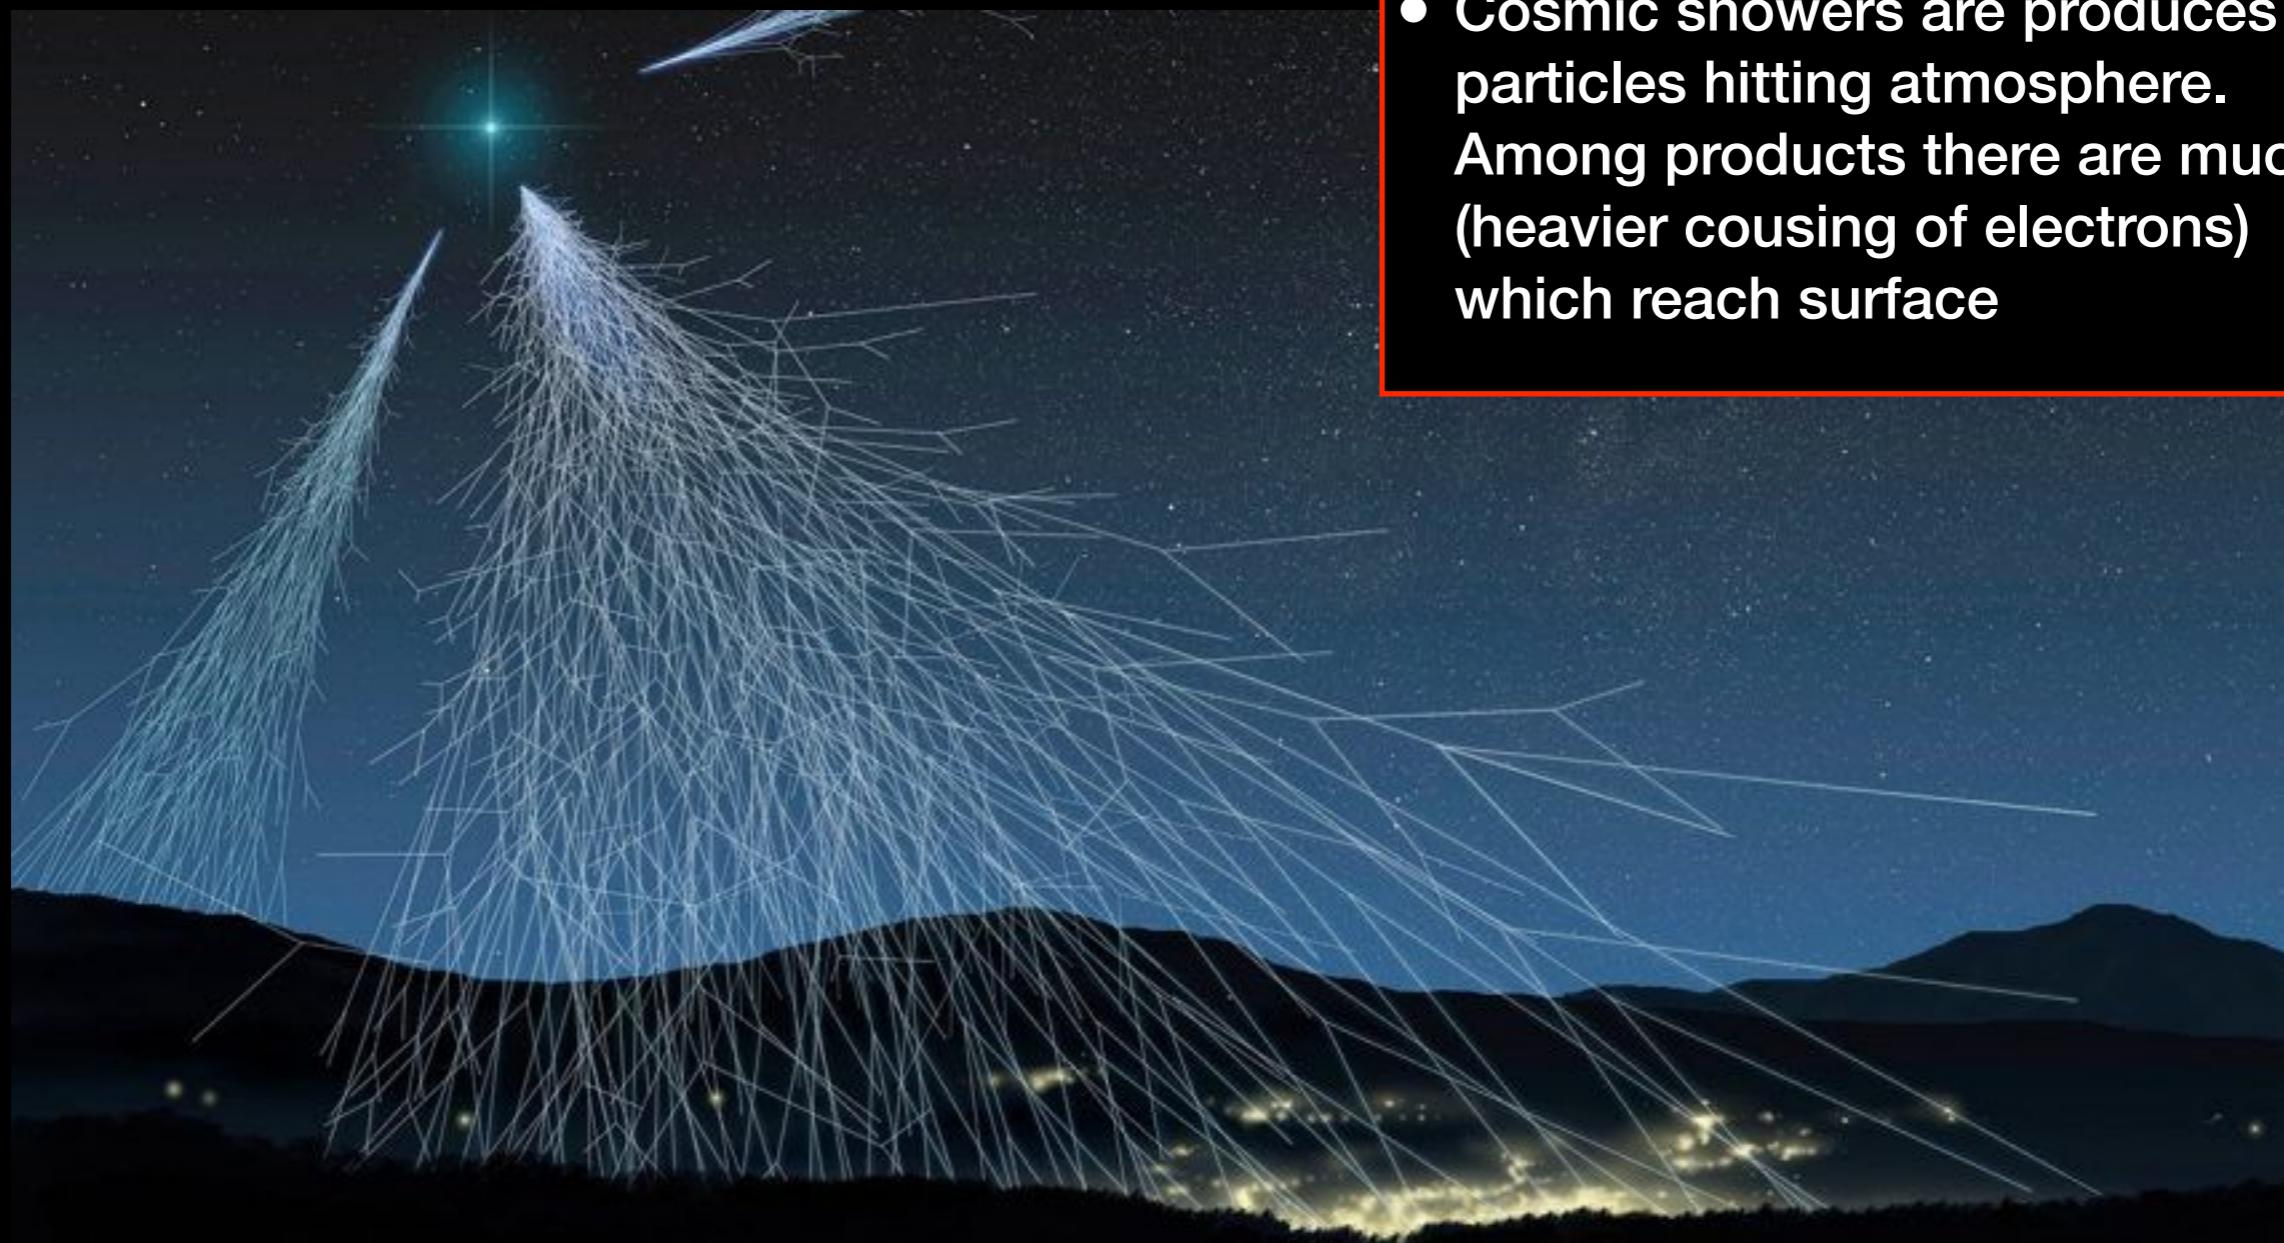

A recipe

- Build a massive “tank” of nuclei
- Hide it underground
- Wait for dm particle to hit the target material
- Look for the response from the hit nuclei

Why underground?

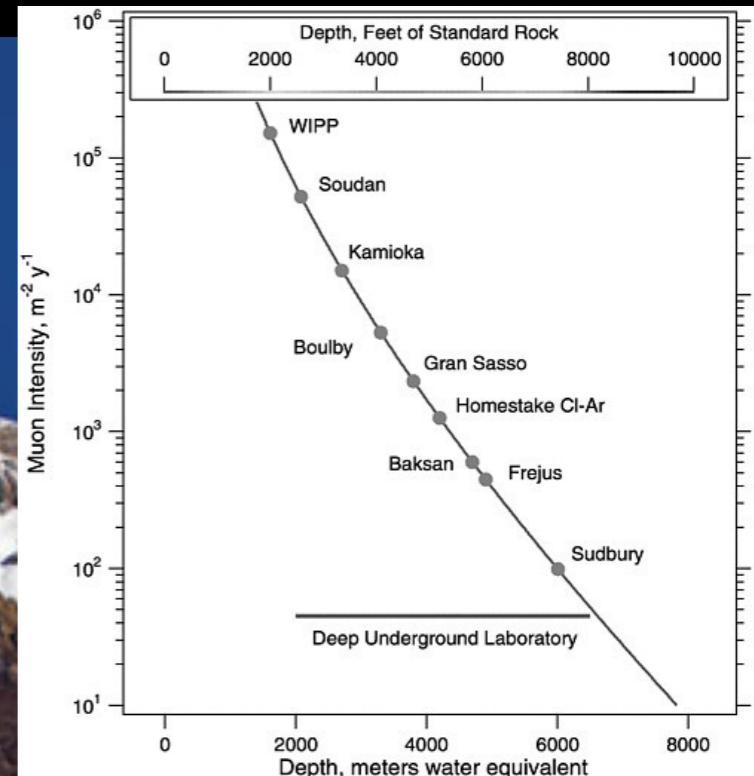

Cosmic rays

- Atmosphere is extremely alive with particles
- Cosmic showers are produced from particles hitting atmosphere. Among products there are muons (heavier cousins of electrons) which reach surface

An underground lab in Italy

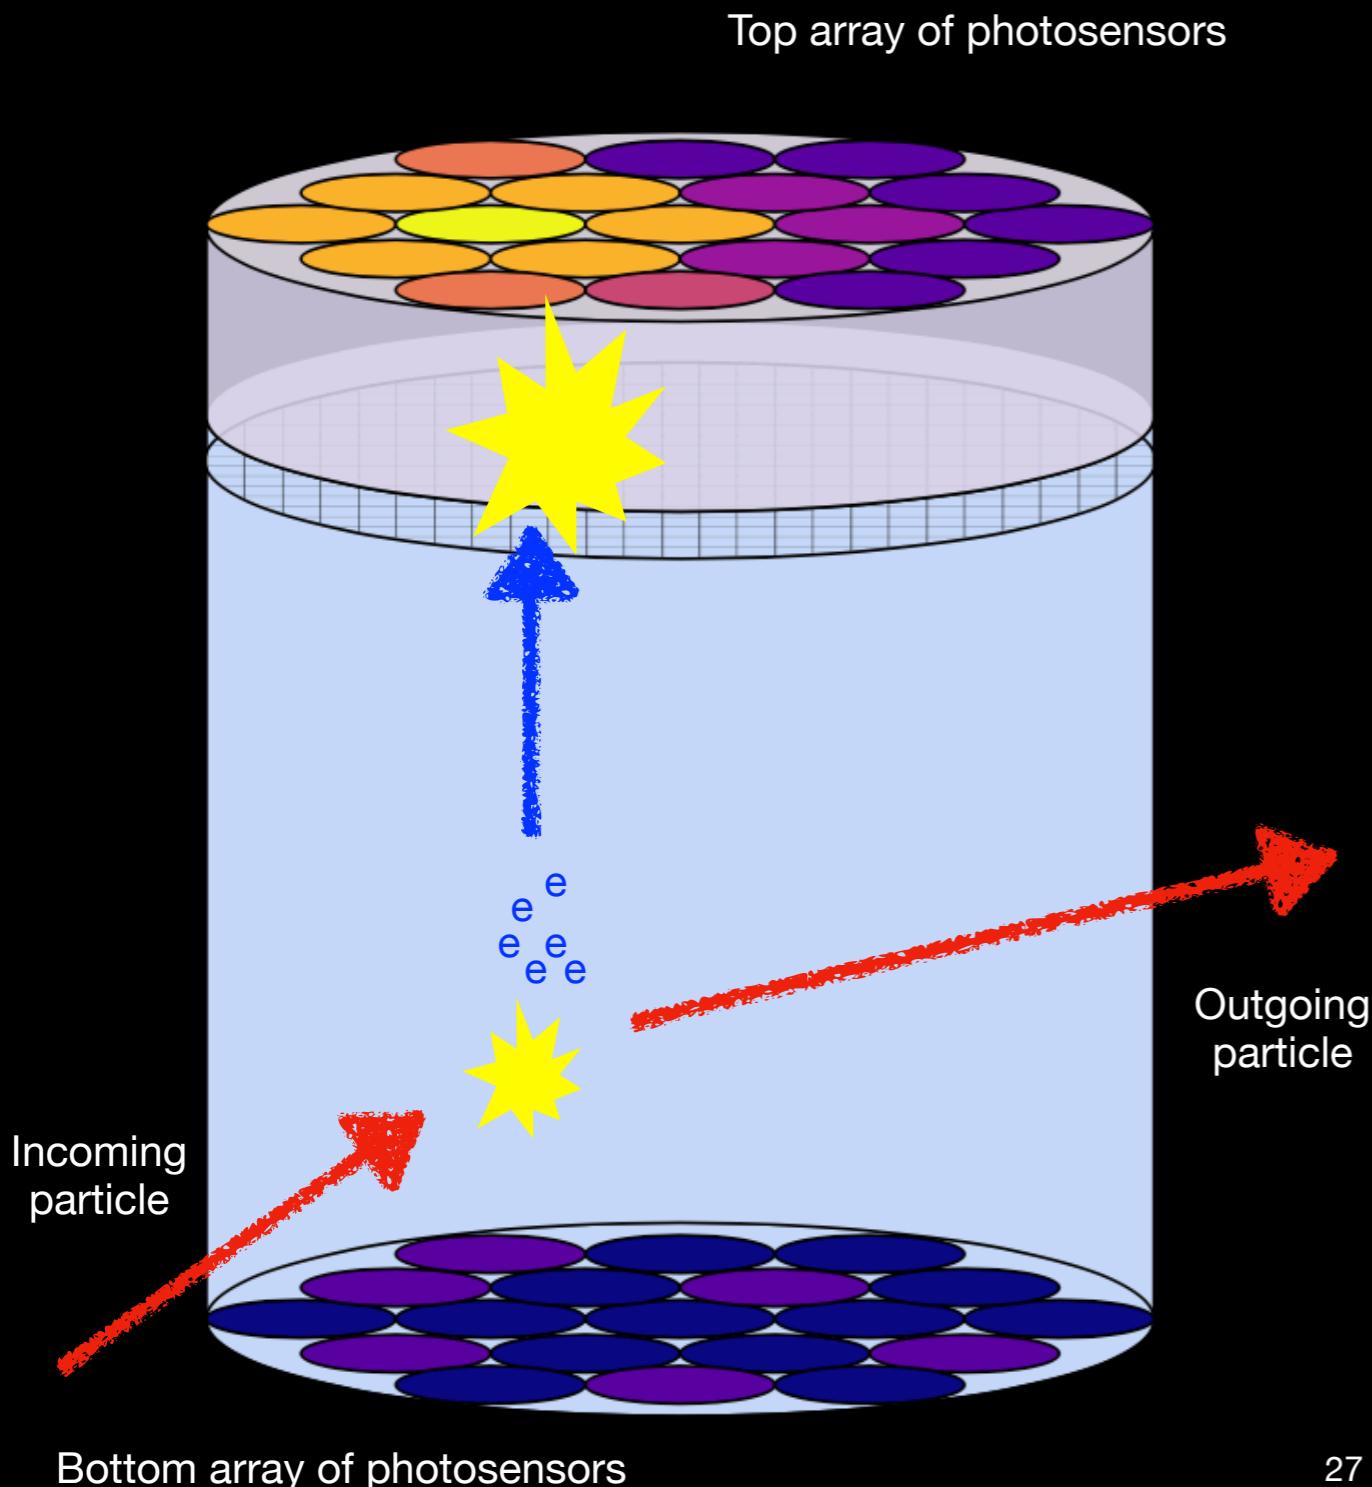

Laboratori Nazionali del Gran Sasso

- Place experiment under a mountain: natural filters for all the muons to have a “quite” environment
- Note: dm is very elusive (do not care for a mountain or even a planet!)

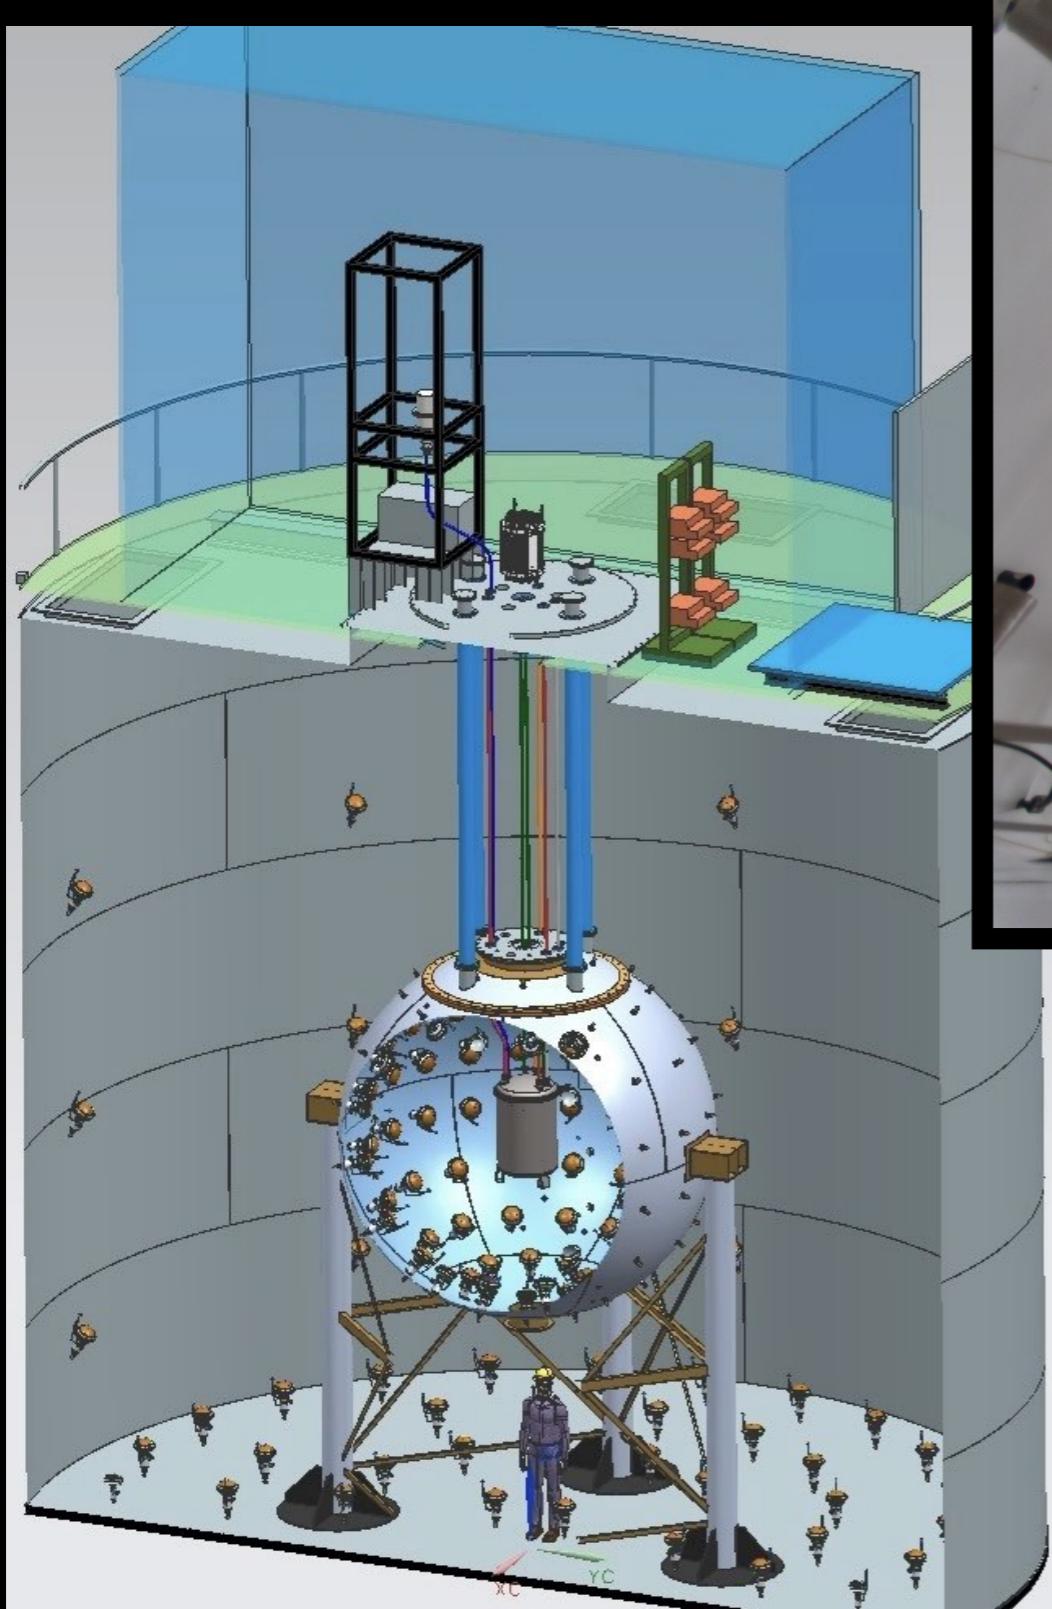

An example: The DarkSide-50 detector

How to detect dm

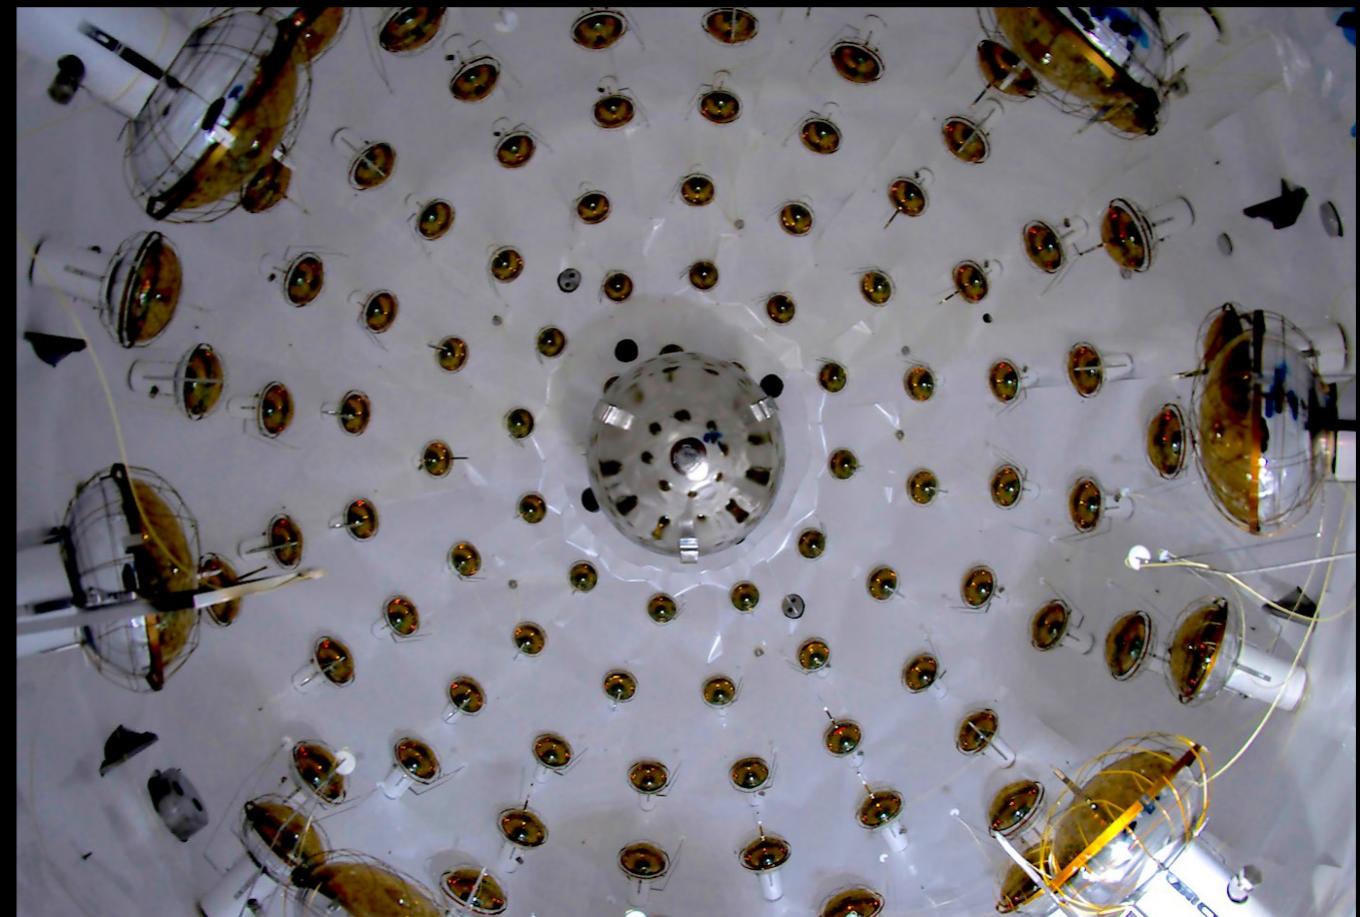

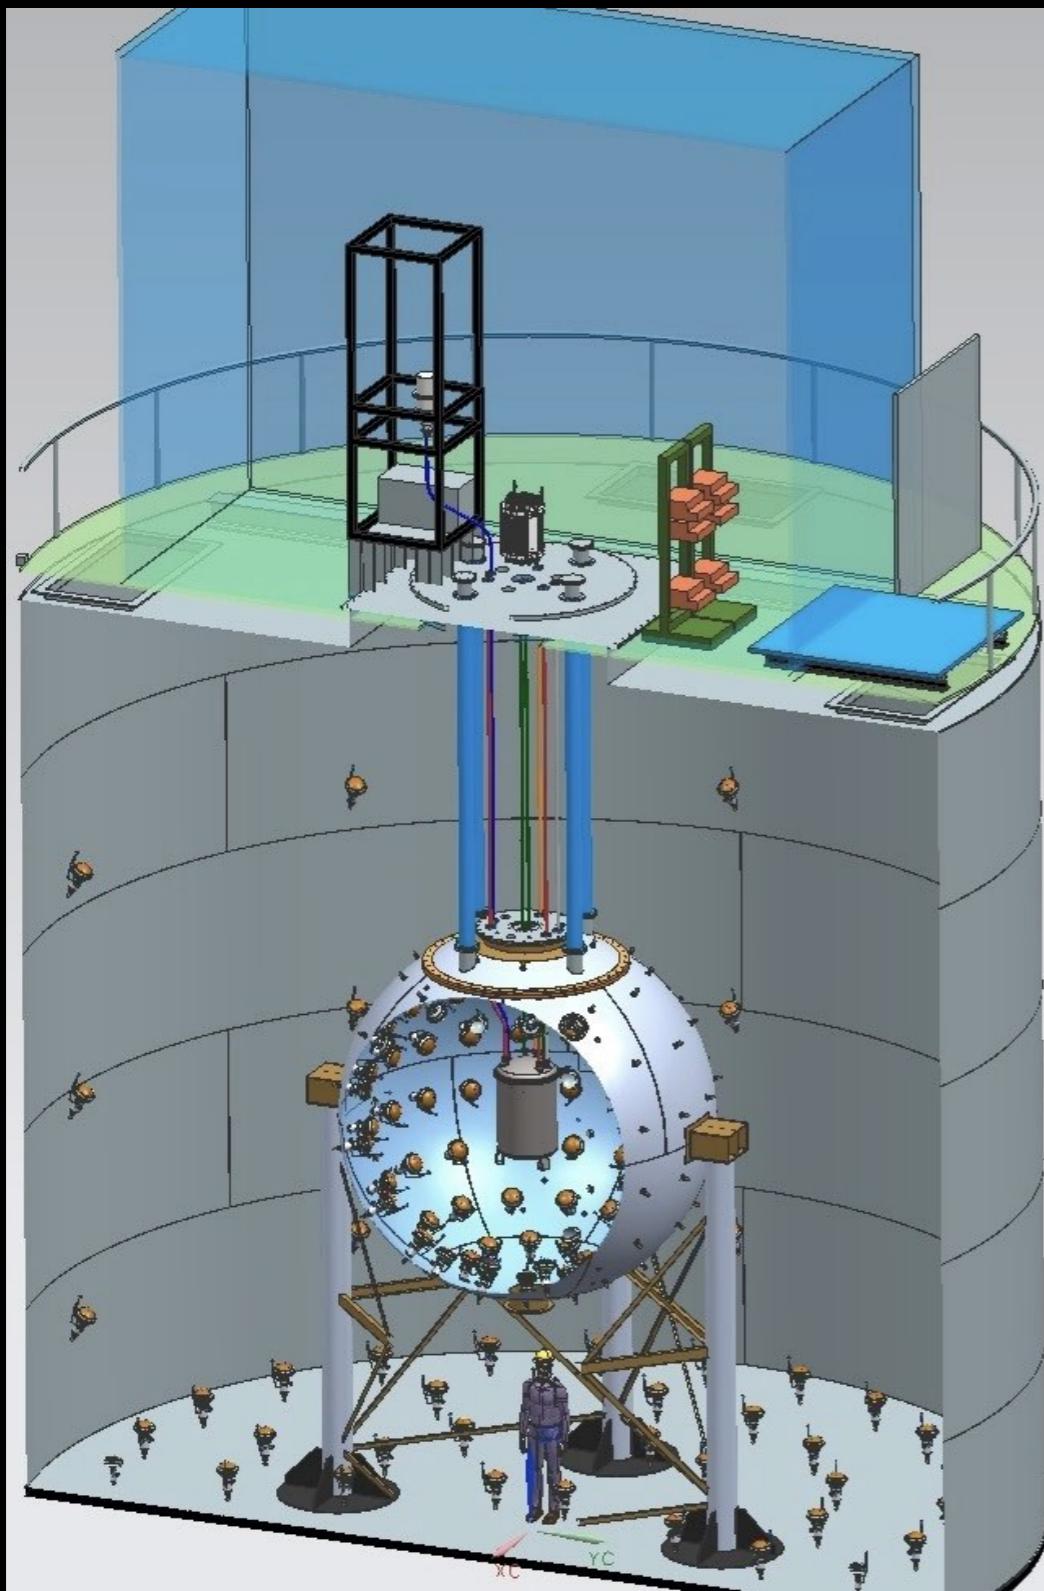

- Housed in LNGS lives the DarkSide-50 detector
- Bucket of liquid argon (~50kg) which detect dm by seeing light
- Incoming particles bump argon atoms producing direct light and electrons
- Electron drifted (by electric field) into gas region producing secondary light
- Very sensitive detector because:
 - Can discriminate among particles
 - Can 3D reconstruct the interaction (time difference between light signals + light pattern on top)

An example: The DarkSide-50 detector

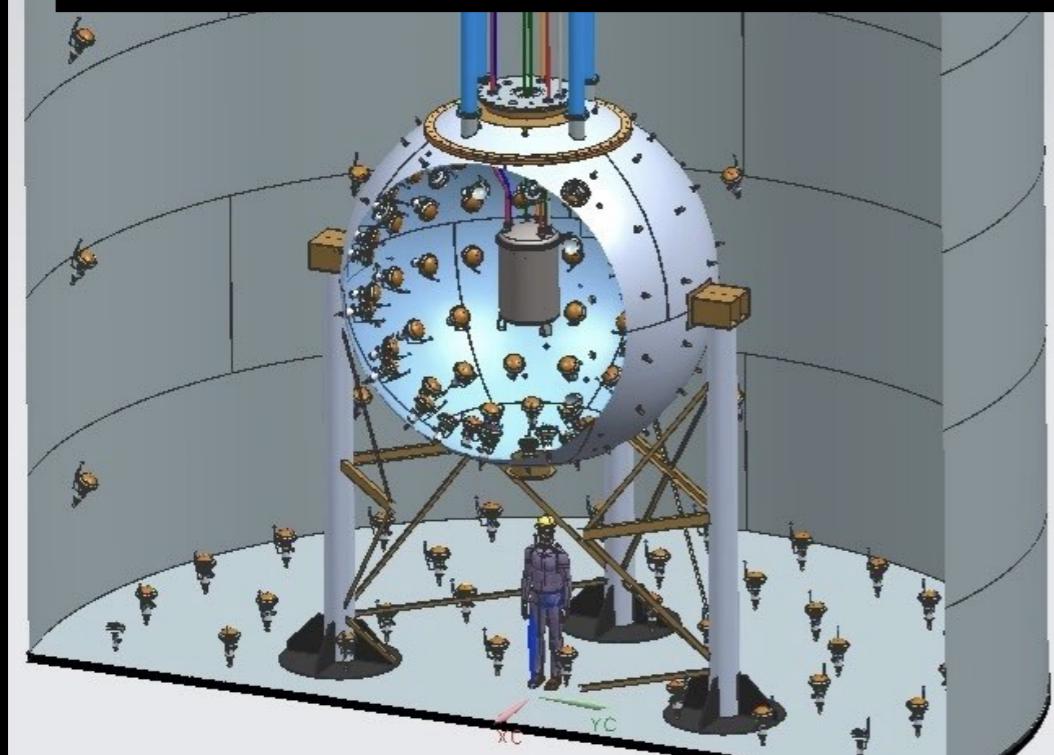

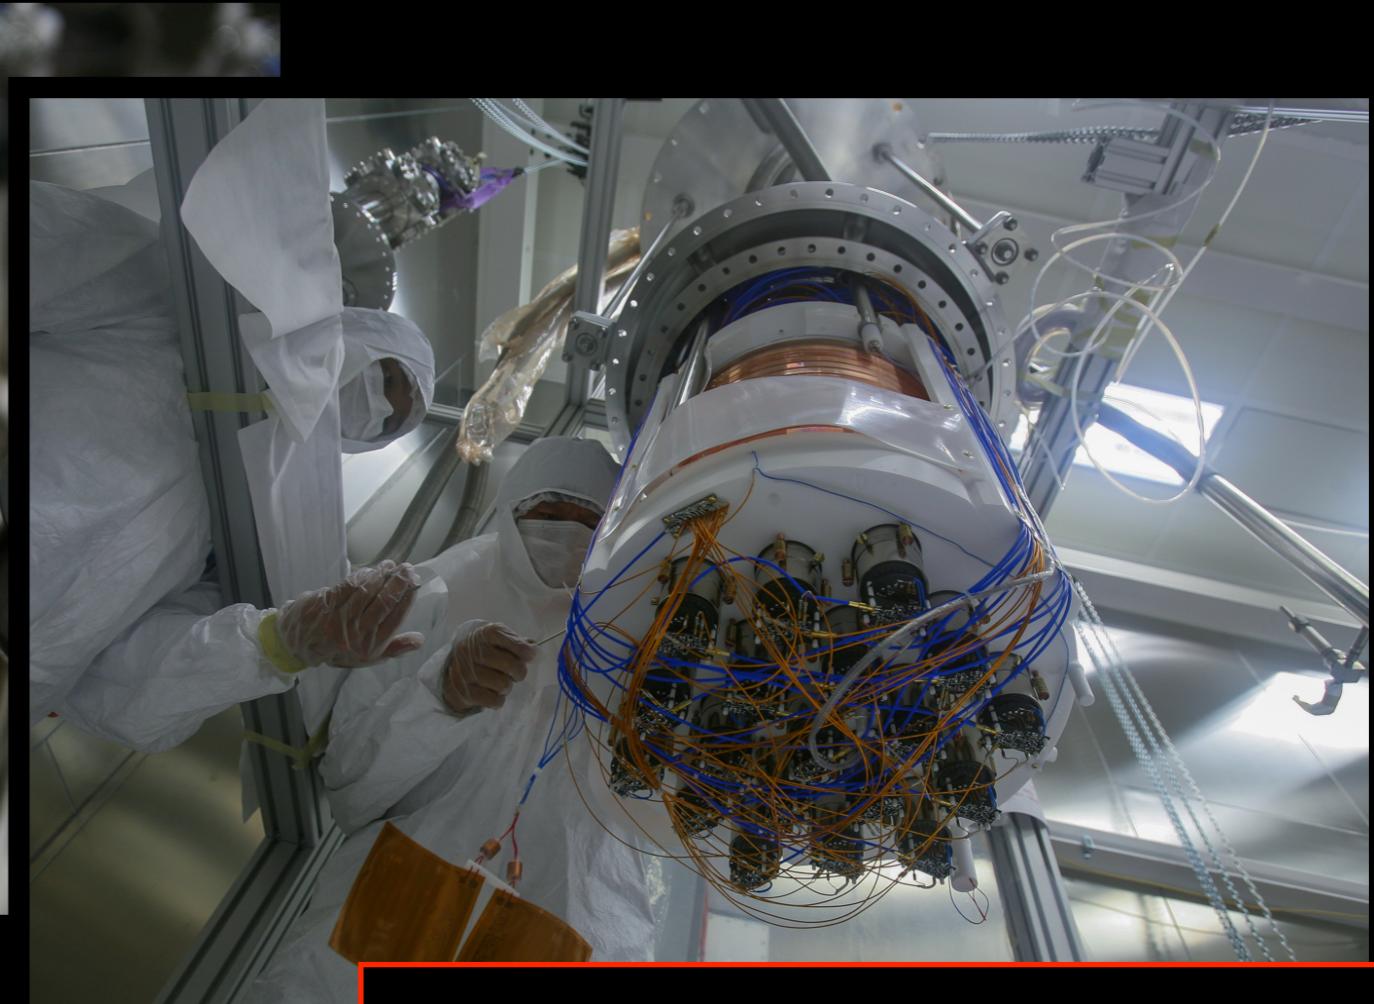

- Muon detector/veto to identify muons deep underground
- 1000L water tank acts as passive shield against radiation, and muons

An example: The DarkSide-50 detector

- Neutron detector/veto to identify neutrons which can mimic dm
- 30 ton liquid scintillator doped with boron (“likes” to capture neutrons)

An example: The DarkSide-50 detector

- 50kg liquid argon bucket seen by top and bottom light sensors. It is the dm detector
- Some numbers: on Earth there are ~3 dm particles per liter which streams through Earth at ~150 miles/s. ~1 billion dm particles every year, but dm is very elusive

Take home messages

- We know dark matter exist because we see its effect in galaxies, clusters of galaxy, and in the Universe itself
- But ...
 - we do not really see it directly
 - we do not know much about it
 - and we haven't discovered it directly yet (maybe in the next 20 years).
- The little we know is that it is extremely elusive and we need big and quite detectors to record such a faint blip

Galaxies are missing some matter

Rotation curve measurements: a little history

- In 1970s Vera Rubin observed Andromeda galaxy stars were rotating too fast
- Not taken seriously for decades but she made the original measurements of dm

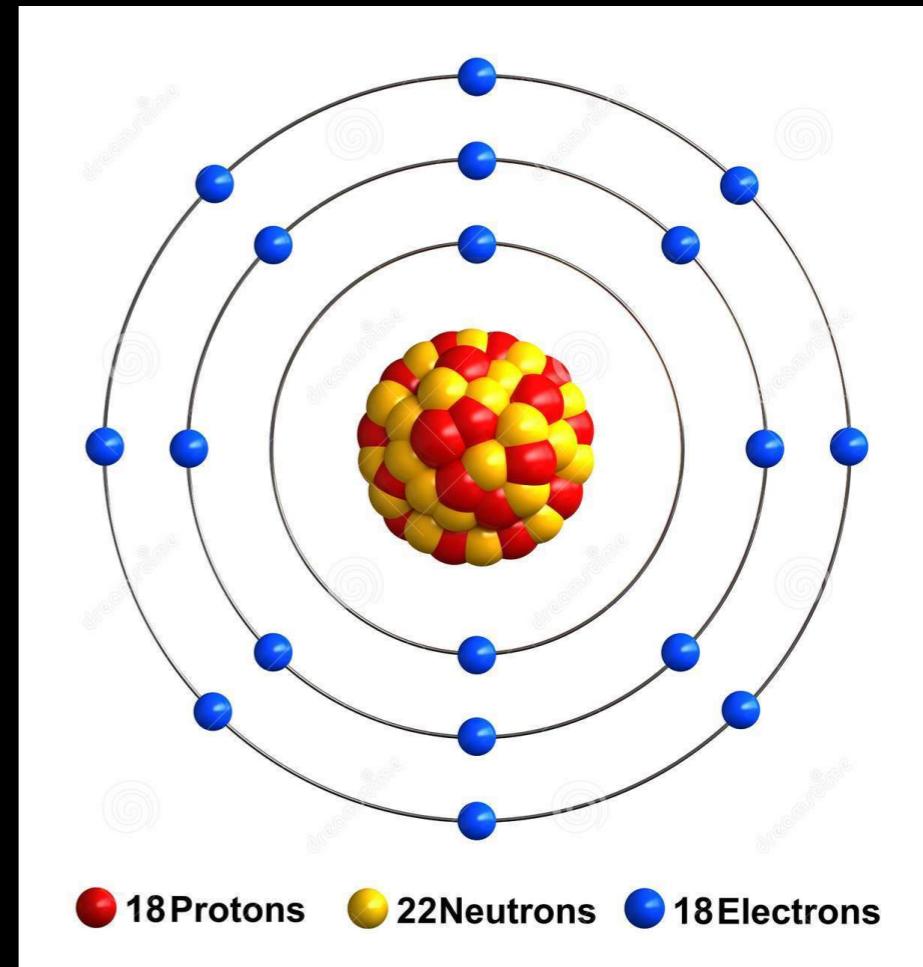

Why argon? And why a liquid?

- Kinematic matching with dm
 - Study an object you cannot see by “throwing” stuff at it: projectile needs to be same size as the object

Why argon? And why a liquid?

- Kinematic matching with dm
- Decent amount of nucleons (proton+neutron)
 - Dm interactions via Nuclear Weak Interactions
 - The more targets (nucleons) the better

Why argon? And why a liquid?

- Kinematic matching with dm
- Decent amount of nucleons (proton+neutron)
- Transparent to its own light
 - Excited noble gases emit (UV) light which can escape and be detected by a light sensor

Why argon? And why a liquid?

- Kinematic matching with dm
- Decent amount of nucleons (proton+neutron)
- Transparent to its own light
- Can be a liquid (at -303F or -186C) so it “easy”
 - To purify: the purer the better
 - To scale: to make a bigger detector just use a bigger bucket (easier said than done)

Dark matter numbers

Dark matter is very very elusive

- Onion-like DarkSide-50 design to detect dm
- Some numbers:
 - ~3 dm particles per liter on Earth
 - dm streams through Earth at ~150 miles/s
 - ~10,000 dm particles at anytime crossing detector volume in ~10 microseconds
 - ~1 billion dm particles every year
 - We hope to detect ~1 per year (if we are very lucky) ... but we did not do it yet!

Take home messages

- We know dark matter exist because we see its effect in galaxies, clusters of galaxy, and in the Universe itself
- But ...
 - we do not really see it directly
 - we do not know much about it
 - and we haven't discovered it directly yet (maybe in the next 20 years)
 - The little we know is that it is extremely elusive and we need big and quite detectors to record such a faint blip
